Presented by invitation, at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Pathology and Clinical Pathology May 5 1949

* Present address Veterans Hospital, Tucson, Arizona.

found without similar involvement elsewhere, the reverse is rarely true One rarely finds diverticula of the esophagus or the duodenum, for example, without having concomitant diverticulosis coli.

The classification of diverticula into a true or congenital type and a false or acquired type on the basis of whether or not all the elements of the intestinal wall enter into its structure has always seemed to me a rather artificial one Careful study will reveal many diverticula which represent intermediate forms—forms which retain, to a variable degree, some of the elements of the muscularis propria It is perhaps more logical, then, to speak of these outpouchings as complete or incomplete rather than false and true, the final form depending on the completeness with which the muscular coat is penetrated. If such is the case, it is not illogical that at some point a partially evaginated or "frustrated" diverticulum may find its path of least resistance to be in the direction of propagation *between* the muscle coats rather than *through* them into the subserosa. Infection of such a diverticulum would then give rise to the features observed by Dr Cohen It may be expected further that in some instances an intramural or incomplete diverticulum need not, of itself, dissect between the muscle coats. It may merely become infected and this infection then spread and burrow in a longitudinal or circular direction between the layers of the gut wall. In such cases the infection or abscess would be dissecting but not the diverticulum. To be sure that the diverticulum itself had actually dissected one would have to demonstrate the presence of the mucosal elements of the diverticulum in the area of dissection. There might be, thus, some question whether one of Dr Cohen's colonic cases represented a dissecting diverticulum or merely dissecting infection arising from an incomplete diverticulum. There can be no question, however, concerning his beautifully demonstrated dissecting diverticula of the appendix.

I doubt very much that a clinical distinction of the dissecting type of diverticulum in the colon or appendix can be made Apparently, it is possible in the esophagus. If Dr Cohen's intriguing hypothesis that the Rokitansky-Aschoff sinuses of the gallbladder are, in reality, also dissecting diverticula, then the condition may be diagnosed here also In retrospect, I have seen one or two instances in which a double contour of the gallbladder was demonstrable roentgenographically, and it is now evident that the appearance was due to entry of contrast material into these sinuses or, if you prefer diverticula It may be that careful study of x-rays of the barium-filled colon and appendix for such a double contour may similarly permit suspicion of the presence of intramural diverticulation.

One other observation may be made. There is a conception that diverticula tend to occur at points of weakness created by entry of vascular channels into the bowel wall. It is sometimes argued against this that, if such were the case, the proximity of blood vessels would give rise to hemorrhage as a frequent complication of diverticulitis It is maintained that such hemorrhages do not occur In point of fact we have had several such instances at the Long Island College Hospital, that is, combinations of acute diverticulitis and hemorrhage. In one such patient in whom hemorrhage had caused death, it was possible to demonstrate pathologically the erosion of the wall of a small artery as it passed from the subserosa through a defect in the muscle in which the ulcerated base of a diverticulum lay

---

PRICKLY HEAT CAUSE FOUND BY DOCTORS

Medical scientists at the University of Pennsylvania have announced they have found the cause of the common skin irritation known as prickly heat The skin condition is caused by perspiration being trapped within the sweat ducts, said Dr Donald M. Pillsbury, chairman of the school's department of dermatology and syphilology This was demonstrated, he said, over a two-year period in which 32 normal, healthy men volunteered to have prickly heat created in them artificially

When perspiration becomes trapped in the sweat ducts, Dr Pillsbury said, cells at the skin's surface become swollen and the patient has what doctors diagnose as "miliaria rubra," or what the layman calls prickly heat. It is an acute inflammation of the sweat glands, characterized by rashes of red papules, or skin elevations, and sometimes by blisters Its itchy, burning discomfort has plagued mankind from infancy

Dr Pillsbury, working with Dr Walter B Shelley and Dr Peter N Horvath, admitted that no cure for prickly heat was found during their experiments

FIG 4 Early organization of alveolar exudate ote coal pigment within granulation tissue and uckened interalveolar septa (Low power, hema- xylin-eosin stain)

attered, small islands of normal lung tissue were served. The remaining areas presented severe athologic changes Several alveoli were distended y intact red blood cells which, in places, were inter- ixed with fibrin In large areas the alveoli and ronchioles were occluded by plugs consisting of red lood cells, fibrin, and large phagocytes studded with lack or gray-brown pigment (Figs 1, 2) In places ie pigment was so abundant that cell outlines were bliterated The alveolar lining was markedly yperplastic, and in areas the lining cells contained igment and were partially or completely cast off Fig 3) All stages of organization of the alveolar ontents were seen Few delicate fibroblasts with ecrete young congested capillaries marked the arly stages of organization, and dense scar tissue ex- anding into adjacent alveoli represented the final ages (Figs 4, 2) Throughout this tissue numerous dust cells" or free pigment were noted The inter- lveolar and interlobular septa were thickened in all ections, mainly due to a marked congestion of the apillaries and in many areas due to strands of dense yalinized tissue (Figs 1, 5) Also in the septa there as an abundant amount of pigment In a few small areas the organization was advanced to such a degree that the normal outlines of the lung architecture were obscured, and only foci of diffuse fibrosis were seen with a heavy infiltration of pigment (Fig 5) In two subpleural areas the fibrosis was of a nodular character There was a general marked perivascular and peribronchial fibrosis, and many lymphatics were occluded by pigment-filled phago- cytes and free pigment (Fig 1) In places capillaries and arterioles appeared to be compressed by the surrounding dense fibrous tissue Many arterioles and small arteries showed a considerable thickening of the intima with a narrow and eccentric lumen (Fig 6) Minute areas of recent hemorrhage were also seen within the thickened septa and alveoli A few small foci of acute bronchopneumonia were scattered throughout the parenchyma. Where alveoli were empty, signs of emphysema and slight bronchiectasis were noted The pleura was markedly thickened, and the pleural lymphatics were distended or occluded by pigment-filled phagocytes and free pigment After microincineration a large number of silica crystals were observed in sections taken from various areas of the lung The crystals were dif-

was markedly emaciated No free fluid was found in the pleural cavities The heart was markedly enlarged and weighed 690 Gm The apex of the heart was at the level of the sixth intercostal space in the anterior axillary line, and all chambers were considerably dilated The thickness of the right ventricular wall measured 0 7 cm and that of the left 1 8 cm The cusps of the mitral valve showed moderate thickening of the free margin, while the leaflets of the aortic valve contained many sclerotic plaques, and one leaflet was deformed The aortic arch presented moderate longitudinal wrinkling

The external surface and cut surfaces of the lungs showed considerable gray-black mottling, and the linear markings were more prominent than average The right middle and lower lobes contained circumscribed areas of consolidation and were cut with increased resistance In the upper lobes the pleura was markedly thickened, and the parenchyma showed a few firm miliary nodules with a black center surrounded by grayish-white tissue. The mediastinal, hilar, and mesenteric lymph nodes were considerably enlarged and anthracotic with uniform fine architecture of the cut surface

The remaining organs were without any appreciable pathologic changes

hard carbon, the probable result of charred binder While this sand is for the greater part uncombined silica (silicon dioxide), some of it does exist as the combined form (silicate) containing aluminum, iron, and calcium. The existing carbon increases from 5 31 per cent in the original sample to approximately 30 per cent in that portion passing a number 200 mesh screen."

Comment

The silicotic changes produced by prolonged inhalation of dust in this case presented the picture of an extensive patchy organizing pneumonia with only very few small subpleural fibrotic nodules and minute areas of diffuse fibrosis The early stages of this process resembled the "anthracotic desquamative pneumonia," a particular type of silicosis, described by Schmidtmann and Lubarsch, where the dilated alveoli were filled with 'dust cell," erythrocytes, and a protein-like material [5] Besides the pneumonic changes, the most prominent histologic features were the marked thickening and collagenization of the interalveolar and interlobular septa and the perivascular and peribronchial fibrosis An abundant amount of free and phagocytosed coal pigment and a large number of silica crystals were demonstrated

In spite of the atypical histologic picture, the chemical examination of the lung showed the extremely high value of 61 4 mg of free silicon dioxide per Gm of dried lung tissue This analysis shows how important the chemical analysis of the lung tissue is when the occupational and clinical history arouses the suspicion of silicosis Although a high silica concentration does not necessarily prove that the patient died from the direct or secondary results of inhalation of dust, the determination of silica values represents a diagnostic procedure of considerable value and may be the closing link in the chain for establishing a definite diagnosis of silicosis [9] Particularly in atypical and doubtful cases like the present one, the chemical analysis is imperative in order to secure for the relatives of the deceased the financial compensation and help of the state, which they deserve A pathologist who is not silicosis minded may overlook atypical histologic pictures without determination of the silica concentration in the tissues

No evidence of tuberculosis was detected, and, therefore, this case is one of pure anthracosilicosis This is another proof that these two diseases can exist independent of each other and that silicosis patients may die from the disease alone or from secondary cardiac failure

The lumina of many pulmonary arterioles were markedly narrowed or occluded due to a thickening of the intima In addition, there was an old rheumatic endocarditis and valvulitis of the aortic and mitral valves with deformity of the aortic valve and dilatation and hypertrophy of the right and left ventricles The clinical course showed that the treatment which was mainly directed against cardiac decompensation gave the patient only temporary relief It can, therefore be assumed that the symptoms were mainly caused by the pulmonary embarrassment The final cause of death was apparently anoxemia due to the extensive silicotic changes of the lungs and subsequent cardiac failure

A review of the literature on the pathology of the pneumoconioses discloses very few similar cases Hackmann in his material described pulmonary alveoli which were plugged by pigment-filled cells and a granulation tissue containing a large amount of pigment [10] Large areas of organization and carnification, thickening of the vascular intima, and obliteration of the pulmonary arterioles were also mentioned Most of his cases, however, also showed extensive nodular fibrosis and tuberculosis According to Bergstrand, in severe cases of silicosis, exudation into the alveoli may occur which may progress through organization into carnification [11] In his opinion this process is solely due to the effect of silica and not due to an intercurrent infection Riddel, Jephcott, and Irwin reported the case of an uncomplicated silicosis in a forty-two-year-old sandblaster who died after six years exposure [12] They found most alveoli filled with an inspissated, pigment-containing exudate, and the septa markedly thickened There was no evidence of infection

According to Gardner, Belt, Cummins and Sladden, and others, the thickening of the septa and the peribronchial and perivascular fibrosis represent the early stages of pneumoconioses but are not considered specific for silicosis [4,6,7 13] It is difficult to understand why, in the present case, in spite of a definite exposure of at least twenty years, the process did not progress into the typical nodular or diffuse fibrosis As a possible explanation, Sweany's observation is quoted—that the inhalation of coal or other mixed dusts together with silica seems to retard the development of typical nodular fibrosis [6] Lanza also stated that the silica content of anthracotic lungs may become twice as high or higher than the level at which silicosis usually develops, before the typical changes of silicosis become apparent [14] There was certainly a marked anthracosis in our case

However, this form of silicosis has been described previously In 1930, Simson *et al* mentioned that in cases of advanced silicosis the fibrosis may be localized in the interstitial septa and bronchioles and that the typical nodules may be absent [15] According to Pancoast and Pendergrass, there are cases of "early interstitial pre-

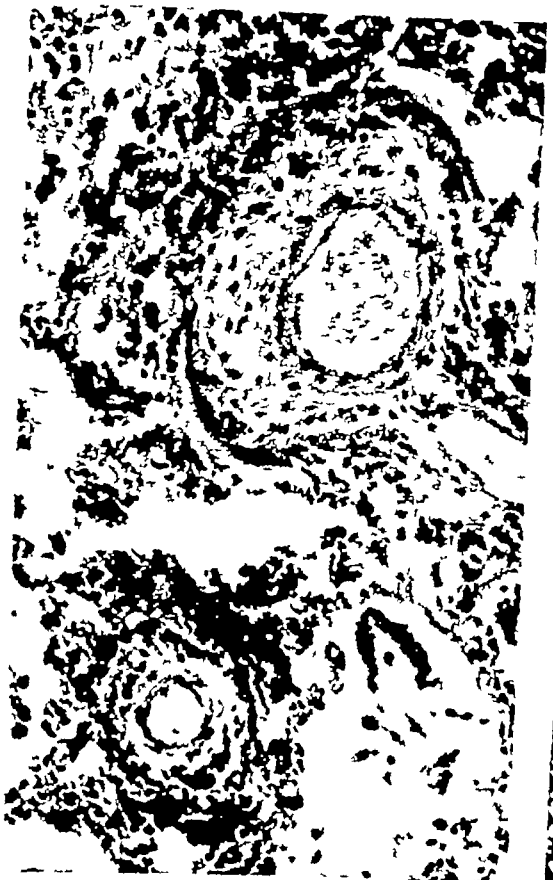

FIG 6 Thickening of the intima of small pulmonary vessels (Low power, hematoxylin-eosin stain)

fusely scattered over the slides or showed areas of dense conglomeration (Fig 7)

Lymph Nodes —Sections taken from several hilar and mediastinal nodes showed diffuse anthracosis Only a few small foci of normal lymphoid tissue were observed. No diffuse or nodular fibrosis was noted

Heart —The myocardial fibers were hypertrophic There was an old rheumatic endocarditis and valvulitis of the mitral valve One thickened leaflet of the aortic valve consisted of dense fibrous tissue The coronary arteries showed slight intimal thickening

Aorta —There was an old luetic mesaortitis and slight atherosclerosis

Liver —Acute and chronic passive congestion with atrophy of the central liver cell cords were present.

The remaining organs showed no essential pathologic changes

Chemical Analysis of the Lungs —The chemical analysis of the lung was as follows

Acid insoluble ash	67 4 mg /Gm. dried lung
Silicon dioxide	61 4 mg /Gm. dried lung
Hydrofluoric acid residue	6 0 mg /Gm dried lung

Examination of Molding Sand.—Sample of sand was collected at foundry where deceased was employed for ten years, analysis was as follows

Silica as silicon dioxide	88 31 per cent
Iron and aluminum as ferric oxide and aluminum oxide	4 76 per cent
Lime as calcium oxide	1 62 per cent
Ignition loss (carbon)	5 31 per cent

Two per cent of the sand passed a number 70 screen Particle sizes of that portion passing number 200 screen is as follows 65 5 per cent—2 micra, 21 5 per cent—10 to 5 micra, 13 0 per cent—5 to 2 micra.

"This apparently is a typical foundry sand with well-rounded grains. These grains are incrusted with

A REVIEW OF THE DIAGNOSIS OF MALIGNANT CELLS IN SEROUS FLUIDS, SPUTA, AND BRONCHIAL SECRETIONS

ANTHONY B CONSTANTINE, M D , and DOROTHY N SHAVER, M D , Buffalo, New York

(From the Pathology Departments of the Buffalo General Hospital and the University of Buffalo School of Medicine)

A REVIEW of the routine examination of body fluids and secretions submitted to this laboratory for tumor cell diagnosis has as its primary purpose the evaluation of the effectiveness of the procedure The present report includes the peritoneal and pleural fluids, the sputa, and aspirated bronchial secretions for the years 1946 through 1948

Materials and Methods

The examination of peritoneal and pleural fluids was made on sectioned sediments prepared and stained like tissue sections When sputa and bronchial fluids were first submitted, familiarity with this method encouraged us to make similar preparations All fluids and secretions were fixed in 10 per cent formaldehyde in approximately 1 part formaldehyde to 5 parts fluid It was requested that the fixative be added immediately after the specimen was obtained either on the ward or at the clinician's office or, if this could not be conveniently done, that the specimen be sent to the laboratory as soon as possible after it was obtained Immediate fixation is a most important step in the preparation of the specimen The fluids usually stood overnight in 10 per cent formaldehyde, during which time a coagulum may have formed After fixation, the supernatant was decanted and 95 per cent alcohol added to aid in holding the coagulum together and making the specimen easier to handle This mixture was centrifuged and the alcohol decanted The coagulum was run through the same process as a surgical specimen, that is, dehydrated, embedded in paraffin, cut, and stained with hematoxylin-eosin If no coagulum was formed after fixation, the specimen was centrifuged and the supernatant decanted Then 95 per cent alcohol was added to the sediment, and it was centrifuged again The alcohol was decanted, and the material remaining in the centrifuge tube was treated as above In our experience, the advantage of this sectioned sediment method is primarily in preserving clumps of cells and cells in their original acinar or papillary arrangement In a few cases special stains for mucus and melanin were added As a rule, one section was prepared from each specimen

The interpretation of the slides was made by one of four different pathologists who read the routine surgical sections during this three-year period Usually, suspicious or positive slides were studied by two or more of the pathologists in the laboratory The final decision was reached before the clinical history was obtained Unless the slide was obviously positive for tumor cells, a systematic search with the low power lens was made for a period of five to ten minutes Concentration on cellular aggregates rather than single cells was emphasized in the microscopic study

Criteria for Diagnosis of Cancer Cells

In general, the criteria used for the recognition of tumor cells in body fluids and secretions are identical with those pathologists are familiar with in their histologic study of tumor cells These criteria are primarily nuclear alterations and, it should be emphasized, are best assessed when the cells are found in clumps and aggregates They include variation in size and shape of nuclei and in nuclear hyperchromatism, either as a dense solid mass of chromatin or as coarse chromatin granules Giant, bizarre, hyperchromatic nuclei are very significant Increased size and multiplicity of nucleoli are at times helpful Increased nuclear-cytoplasmic ratio is characteristic of cancer cells but at times difficult to assess Mitotic figures are of little practical importance, since they are not commonly seen, and, when found, cancer cells are so numerous that the diagnosis is obvious immediately for other reasons An interesting diagnostic criterion in sputa, and especially in bronchial secretions, is the finding of masses of small cells with scanty cytoplasm, uniform size, distinct hyperchromatism, and irregularity in size and shape of nuclei These cells at first glance have the appearance of lymphoid elements, but in our experience have been characteristically small-cell, undifferentiated bronchogenic carcinoma

In pleural and abdominal fluids from patients with a chronic effusion in heart or hepatic disease, mesothelial cells have sometimes caused confusion These cells may appear as giant hyper-

Presented by invitation, at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo, Section on Pathology and Clinical Pathology

dominance" which are characterized by fibrosis of the interstitial lung tissue without marked nodular fibrosis [16] The authors stress the point that these findings may be the only demonstrable lung changes, even in the terminal stages Zur Williams also mentioned that besides the typical nodulation "linear fibrosis" may be observed [17] Johnstone considered the silicotic nodules pathognomonic but pointed out that these nodules may be infrequent or absent, even in the late stages [18] Policard warned against the general tendency to exaggerate the diagnostic importance of the nodular fibrosis, and he did not subscribe to the definition of silicosis agreed upon by the Johannesburg Conference, which declared the fibrotic nodule a criterion for the histologic diagnosis of silicosis [2]

The silica content of the lung tissue from the present case was extremely high Sweany "has never seen a specimen just like it "[19] Only very few cases of similar or higher values were reported in the literature The lungs in Hackmann's Case 9 contained 8 46 per cent silicon dioxide, Case 25, 6 63 per cent, and Case 32, 6 52 per cent [10] Fowweather reported one case with 6 25 per cent silica [20] King examined several specimens of lung tissue and found values of 63 mg , 60 mg , and 123 55 mg of silica per Gm of dried lung tissue, but no clinical or histologic data were given [21] McNally asked that in all autopsies a chemical analysis of the lungs should be performed if the deceased had a history of prolonged exposure to fine dust [22] On the other hand, Gardner and Redlin point out that the routine chemical analysis of the lungs yields only the amount of total silica, which is unimportant, since only the free silica is pathogenic and silicates are harmless [23] A high silica content, therefore, does not mean that the patient has silicosis if the histologic changes do not bear out this diagnosis In our case, the analysis of the sand showed that the patient was exposed to a high concentration of free silica

Obstruction of the pulmonary vascular system was described by Kettle, Matz, and Sweany *et al* [24 5 6] All 23 cases reported by Matz showed marked cardiac hypertrophy and dilatation caused by gradual obstruction of the pulmonary circulation [6] According to Kettle, the greatest danger for cases of simple uncomplicated silicosis lies in cardiac failure due to obstruction of the pulmonary arterioles [4] Sutherland, Strachan, and Simson, however, do not believe that the pulmonary endarteritis is an essential feature of silicosis, and they have never observed cardiac hypertrophy caused by silicosis [1]

Summary

An unusual case of anthracosilicosis in a forty nine-year-old molder has been described with complete autopsy findings, The exposure to fine dust exceeded twenty years The lungs presented a picture of an extensive patchy organizing pneumonia with considerable linear fibrosis. Only a few small subpleural fibrous nodules were present The chemical analysis showed 6 14 per cent silicon dioxide of dried lung tissue The unusual features of this case were discussed and compared with similar observations in the literature The importance of the chemical analysis of the lung tissue in definite and doubtful cases of silicosis was stressed

I am grateful to Henry C Sweany M D , Municipal Tuberculosis Sanitarium Chicago for the chemical analysis of the lung tissue to C M Blumenfeld, M D Cleveland for the microincineration and to Mr E J Kunde Cleveland for the analysis of the foundry sand

ers are considered (Table 1) No false positive puta diagnoses were made

BRONCHIAL ASPIRATION —Forty bronchial und specimens from 36 cases were observed hese 36 cases included 13 with histologically roved bronchogenic cancer and five with clinical r x-ray-suspicious cancer The remaining non-eoplastic cases included bronchiectasis, chronic ronchitis, asthma, tuberculosis, lung abscess, npyema, congestive heart failure, etc , as in the puta cases Seven cases with seven positive ronchial secretions were observed Of these even positive secretions, six came from histologally proved cancers, one came from a clinically nd x-ray-diagnosed case of bronchogenic cancer hus, 38.8 per cent (7/18) of both the clinically uspicious and proved bronchogenic cancers were ositively diagnosed by bronchial aspiration, 1 per cent (6/13) of histologically proved cans were positively diagnosed (Table 1)

No false positive bronchial aspirations were reorted

In an attempt to evaluate the effect of the poion of the bronchial cancer on the fluid diagno, 32 sputa and bronchial fluids from proved ases in which bronchoscopy had been done were available Eleven of 19 fluids were positive when the bronchoscopist visualized the tumor, while only three of 13 fluids were positive when the tumor was not visualized

Comment

Comparing the present results with those reported in the literature is difficult for two reasons First, our material was sectioned, while most reports are based on smears Second, the reported results with the exception of those of Liebow *et al* are calculated on a patient or case basis [1] The number of slides or specimens examined per patient has varied from one up to 24 (Herbut and Clerf examined six to 24 slides per patient) [3] It seems to us that reporting results on a case basis leads to difficulty in evaluating the accuracy of different studies unless the number of slides per patient are similar

Becker and Shaver in their study found no false positives [4] They did not analyze the pleural and peritoneal fluids separately but reported 18 positives out of 34 cases with serosal carcinomatosis (52 9 per cent) Combining our two groups, we find 18 out of 33, or 54 5 per cent, positive in cases with serosal carcinomatosis

Papanicolaou, working with sputum smears, reported 18 positive diagnoses out of 27 cases of histologically proved bronchogenic cancer, or 66 per cent positive, 70 per cent positive diagnoses were made in 31 cases of both clinical and histologically proved bronchogenic cancer [2] Liebow *et al* report 42 8 per cent positive sputa smear diagnoses per case (three and two-tenths, average number of slides per patient), while only 15 8 per cent positive sputa diagnoses per slide [1] Wandall, using sputa smears, found 84 per cent positive cases out of 100 cases of proved bronchogenic carcinoma [5]

Herbut and Clerf, studying five to 24 smears per case of aspirated, smeared bronchial fluid, report 47 positives of 57 cases of clinical and histologic bronchogenic cancer, or 82 per cent positives [3] It is difficult to assess Herbut and Clerf's report, since no mention is made of false positives, and it would appear that they made no attempt to evaluate the method on both positive and negative patients McKay and Ware report 74 per cent (40/54) positive bronchial fluid smear diagnoses (per case) using an average of four and one-tenth slides per case [6] Liebow *et al* found 30 per cent (9/30) positive bronchial fluid smears, using one slide per patient [1]

In our study, approximately twice as many positives were obtained in bronchial fluid as compared to sputum A similar ratio was found by Liebow *et al*, while Woolner reported no advantage of bronchial aspiration over sputum [1,7,8]

In most surgical pathology laboratories a positive tissue diagnosis of cancer closely approaches 100 per cent accuracy A false positive histologic diagnosis of cancer is a very serious error for any conscientious pathologist It is then rather amazing to read of the number of false positive sputa and bronchial secretions reported in the literature McKay and Ware gave three false positives out of 116 negative cases, or 2 6 per cent, Liebow *et al* report three false positive sputa out of 59 negative cases, or 4 8 per cent [1,6] Wandall's false positives amount to six out of 66 negative cases, or 9 1 per cent [5] Woolner found three false positives in a series of 150 sputa and bronchial fluids [7,8] Papanicolaou had no false positive sputa diagnoses, and his attitude toward false positive diagnoses is worth repeating "Failure to detect malignant cells in a smear is in a way excusable, but the wrong interpretation of findings is apt to be severely criticized and to cause serious doubt as to the accuracy and dependability of the test" [2] The attitude in this laboratory has always been that specificity should not be sacrificed for sensitivity In our study a diagnosis of cancer cells in a fluid or secretion is highly accurate A single negative report is of no diagnostic importance Only when repeatedly negative fluids or secretions are found in a given case can any significance be attached

Summary

1 Pleural and abdominal fluid, sputa, and aspirated bronchial secretions observed in this

arrangement Evidence of phagocytosis and uniformity in nuclear size and the nuclear-cytoplasmic ratio usually indicate their true character

We feel, and conservative observers emphasize, that the positive diagnoses should rest upon the finding of groups of many frankly cancerous cells Thus, Liebow, Lindskog and Bloomer say, "Reliance was placed only upon groups of cells possessing an arrangement suggesting that of tissue, not merely upon individual atypical cells "[1] Similarly, Papanicolaou states that the diagnosis should be "based on a strong substantive evidence offered by pathognomonic cells and cell groups," and that "one should refrain from reaching a final conclusion on the strength of only a few cells "[2]

Lastly, with the section method which better preserves exfoliated cancerous fragments, the diagnosis not infrequently can be made on a truly histologic basis Papillary and acinar masses of atypical cells can be diagnosed at a glance as malignant

TABLE 1 —NUMBER OF POSITIVE TUMOR CELL DIAGNOSES OBTAINED FROM EXAMINATION OF BODY FLUIDS AND SECTIONS

	Positive	
	Per Case	Per Fluid
Pleural fluid		
Clinical and histologic pleural carcinomatosis	74% (17/23)	71 4% (25/35)
Histologically proved pleural carcinomatosis	50% (6/12)	44% (8/18)
False positive reports	0%	0%
Abdominal fluid		
Clinical and histologic peritoneal carcinomatosis	64% (16/25)	64% (19/30)
Histologically proved carcinomatosis	57% (12/21)	57% (15/26)
False positive reports	0%	0%
Sputum		
Clinical and histologic bronchogenic carcinoma	20% (5/25)	14 7% (5/34)
Histologically proved bronchogenic carcinoma only	33 3% (5/15)	21 7% (5/23)
False positive reports	0%	0%
Bronchial aspiration		
Clinical and histologic bronchogenic carcinoma	38.8% (7/18)	31.8% (7/22)
Histologically proved bronchogenic carcinoma	46% (6/13)	37 5% (6/16)
False positive reports	0%	0%

Observations

PLEURAL FLUIDS —There was a total of 95 fluids submitted from 72 different cases Twenty-five fluids in 17 different patients were reported positive Of these 17 patients, cancer was proved by tissue biopsy usually of the primary tumor in 15 cases In two others there was strong clinical or x-ray evidence of a primary cancer Proof of pleural involvement such as pleural biopsy, surgical exploration, or postmortem examination was available in six of the 17 positive cases, while similar proof of pleural involvement was obtained in six cases reported as negative Thus, out of 23 cases with histologically and clinically probable carcinomatosis of the pleura, a positive diagnosis was made in 17, or 74 per cent (Table 1) Of 12 cases in which carcinomatosis of the pleura was proved, either at surgery, postmortem, or biopsy, six (50 per cent) were diagnosed from the fluid examined The same results, computed per slide rather than per case, showed a total of 25 positive slides out of a possible 35, or 71 per cent The primary cancer site of these positive fluids was known to be the lung in seven, the breast in four, the ovary in three, primary mesothelioma in one, and unknown in one case No false positive pleural fluid was reported

ABDOMINAL FLUIDS —A total of 91 fluids were examined from 72 cases Nineteen fluids from 16 cases were reported positive Of the 16 positive cases, 12 had surgical or postmortem proof of carcinomatosis of the peritoneum, three had a proved histologic cancer and clinical carcinomatous effusion, and one case diagnosed on clinical and x-ray grounds died without autopsy

Eleven fluids from nine cases with postmortem or surgically proved peritoneal carcinomatosis were reported negative

Of the clinical and histologically proved carcinomatosis, 16 out of 25 cases (64 per cent), were diagnosed from the peritoneal fluid (Table 1) If only postmortem or surgical biopsy proved cases of carcinomatosis are considered, 12 out of 21 cases, or 57 per cent, were positive When calculated per fluid rather than per case, the percentages are 64 (19/30) and 57 (15/26), respectively No false positive reports were rendered

The primary site in the 16 positive cases included seven ovary, two stomach, two pancreas, two gastrointestinal tract, unspecified, one primary mesothelioma, one gallbladder, and one cervix

SPUTUM —Sixty-one sputa from 43 cases were examined Of these 43 cases, 15 were histologically proved cancer of the lung, ten cases were x-ray on clinically suspicious bronchogenic cancers In the remaining cases, various nonmalignant pulmonary diseases were diagnosed Cancer cells were found in five cases, two cases had sputa reported as suspicious The five positive cases, as well as the two suspicious, were all histologically proved bronchogenic cancers The percentage of positives calculated on the basis of both the histologically proved and clinically suspicious cases is 20 (5/25) and, on the basis of only the histologically proved cancers, 33 3 per cent (5/15) On a "per slide" basis, 14 7 per cent (5/34) of the clinical and histologically proved bronchogenic cancers were positive while 21 7 per cent (5/23) were positive when only histologically proved can-

NEEDLE BIOPSY OF THE LIVER IN ALCOHOLIC PATIENTS

SAMUEL SANES, M D , ROBERT C BAHN, M D ,* WILLIAM H C CHAPPLE, M D , and NORMAN CHASSIN, M D ,* Buffalo, New York

(From the Departments of Pathology and Medicine, Edward J Meyer Memorial Hospital and the University of Buffalo School of Medicine)

THE problem of the relationship of alcoholism to hepatic lesions is a perennial one Originally, discussion of this problem was restricted to clinical and postmortem findings Added information was later furnished by the introduction of hepatic function tests Lately needle biopsies of the liver have been employed to supply further data on the problem In this respect may be cited several recent publications [1-4]

Material and Methods

We report on 87 needle biopsies of the liver in 80 alcoholic patients By such patients we mean those who were admitted to the alcoholic and psychiatric services, nearly always in acute intoxication and occasionally at the end of a spree, through their own request or by order of the police Ages of the patients ranged from twenty-four to sixty-eight years There were 74 men and six women All patients were chronic, steady, or intermittent drinkers for months to years Forty-five patients had multiple admissions (two to six times) to our hospital for alcoholism It was difficult to get detailed histories of diet, but we could be sure that many patients before admission to the hospital had lived on deficient diets Our biopsies did not constitute a series from consecutive patients, however, patients were not selected specifically for biopsy, although a number were likely chosen by resident physicians because some evidence suggested hepatic disease

To obtain biopsy specimens, we used the Vim-Silverman needle through subcostal or intercostal approach [5] In 62 patients, the liver was palpable below the costal margin Original biopsies were made one to sixty-three days after admission Thirty-eight were made within one week after admission, three were over three weeks after admission After immediate fixation in 10 per cent formaldehyde, biopsy specimens were sectioned by the paraffin method and stained with hematoxylin-eosin Prussian blue reaction was applied to 77 specimens of 72 patients Results for iron-containing pigment were graded as follows Class I—little or no iron pigment, Class II—slight amount of iron pigment, Class III—moderate to distinct amount, and Class IV—marked amount

Concurrently with needle biopsy, we tried to carry out a battery of hepatic function tests on each patient These tests, with abnormal ranges set by us included Van den Bergh test (between 0 5 and 1 mg and over 1 mg per 100 cc), alkaline phosphatase (between 4 and 10 Bodansky units and over 10 units), bromsulfalein test, 5 mg dose (over 10 per cent retention after one hour), serum albumin determination (below 3 5 Gm per 100 cc), albumin-globulin ratio (less than 1), prothrombin level (less than 70 per cent) forty-eight-hour cephalin flocculation, formol gel, colloidal gold and thymol turbidity tests (over 2 plus), hippuric acid synthesis, intravenous (less than 0 7 Gm), and hemoglobin determination (less than 70 per cent) No information in regard to clinical findings or results of function tests was given the pathologist before he completed his microscopic report Each biopsy was described independently by two pathologists

Results

In 80 patients microscopic reports on the original needle biopsy fell in these general groups preserved ("normal") liver, 13 cases, fatty liver, 36 cases, marked fatty liver with cirrhosis, seven cases, portal cirrhosis, 20 cases, unsatisfactory or unclassified, four cases

Preserved ("Normal") Liver (13 Cases) — The patients ranged in age from twenty-eight to sixty-two years with an average age of forty-five years All patients were men Eight showed palpable livers Biopsies were made from two to twenty-one days after admission, the average period was nine days, seven biopsies were made within one week after admission The total number of hepatic function tests was 98 Of these, ten gave abnormal results, all of which were in the borderline range except three Iron pigment was graded Class I, ten cases, and Class II, two cases

Fatty Liver (36 Cases) —In this group the hepatic changes were analyzed as follows slight fatty change, 15 cases, moderate, 13 cases, marked, eight cases

NEW YORK STATE MEDICAL LIBRARY

Doctors of New York State are reminded of the facilities of the State Medical Library at Albany They are invited to visit, telephone, or write to the Library where a trained staff of librarians will take care of their requests

Upon request, a copy of the regulations will be sent, which lists the services of the Library, including the compiling of bibliographies, sending material on specific subjects, or filling requests for definite book or journal references

A collection of over 57,000 books and the receipt of approximately 600 current medical journals enable the Medical Library to offer a real service to the doctors of the State

Letters may be addressed to Miss Maude E Nesbit, Librarian, New York State Medical Library, Education Building, Albany 1, New York.

NEEDLE BIOPSY OF THE LIVER IN ALCOHOLIC PATIENTS

* By invitation

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Pathology and Clinical Pathology May 4 1949

Slight fatty change (15 Cases) —The patients ranged from thirty-six to fifty-nine years with an average age of fifty-three years There were 14 men and one woman Positive physical findings included palpable liver 12, atrophy of tongue four, spider nevi two, palpable spleen one, edema one, and fever one Biopsies were made two to eighteen days after admission, the average period was seven days, eleven biopsies were made within one week after admission The total number of hepatic function tests was 135 Of these, 20 tests gave abnormal results, of which nine were beyond borderline range Iron pigment was graded Class I, ten cases, Class II, four, Class III, one case

Moderate fatty change (13 Cases) —The patients ranged from thirty-one to sixty-eight years with an average age of forty-seven years All patients were men Positive physical findings included palpable liver ten, atrophy of tongue five, edema four, and fever one Biopsies were made one to fifteen days after admission, the average period was eight days, eight biopsies were made within one week after admission The total number of hepatic function tests was 106 Of these, 28 tests gave abnormal results, of which 15 were beyond the borderline range Iron pigment was graded Class I, ten cases, and Class II, three cases

Marked fatty change (8 Cases) —The patients ranged from forty-one to sixty-two years with an average age of forty-nine years Seven patients were men, one patient was a woman Positive physical findings included palpable liver seven, edema one, and atrophy of tongue one Biopsies were made one to thirteen days after admission, the average period was five days, seven biopsies were made within one week after admission The total number of hepatic function tests was 69 Of these 13 tests gave abnormal results, of which six were beyond the borderline range Iron pigment was graded Class I, eight cases

Marked Fatty Liver with Cirrhosis (7 Cases) —The patients ranged from twenty-four to sixty-six years with an average age of forty-six years Five patients were men, two were women Positive physical findings included palpable liver seven, spider nevi two, atrophy of tongue two, palpable spleen one, jaundice one, and edema one Biopsies were made two to twenty days after admission, the average period was ten days, three biopsies were made within one week after admission The total number of hepatic function tests was 62 Of these 31 tests gave abnormal results, of which 23 were beyond borderline range Iron pigment was graded Class I, two cases, Class II, two, Class III, one case

Portal Cirrhosis (20 Cases) —In this group the hepatic changes were analyzed cirrhosis with fat, seven cases, cirrhosis without fat, ten cases, cirrhosis with definite jaundice, two cases, cirrhosis with marked iron pigment one case The patients ranged from thirty-four to sixty-seven years with an average age of fifty years Eighteen patients were men, two were women Positive physical findings included palpable liver, 18, jaundice, nine, edema, nine, ascites, six, fever, four, spider nevi, three, palpable spleen, two, atrophy of tongue, two and neuritis one On clinical grounds eight cases of cirrhosis were judged to be "compensated" and 12 cases "decompensated" The total number of hepatic function tests was 173 Of these, 90 tests gave abnormal results, of which 72 were beyond borderline range Iron pigment was graded Class I, 12 cases, Class II, four Class III, two, Class IV, one case

In the groups designated as "fatty liver" and "cirrhosis" there were varying degrees of regressive parenchymal change, interstitial inflammation, fibrosis, iron-free pigmentation and regeneration

Comment

In discussing the problem of the relationship of alcoholism to hepatic lesions, we face these questions Do hepatic lesions occur with any frequency in alcoholic patients, and, if they do what are their pattern and cause? How may the hepatic lesions best be detected intravitam?

In answer to the first question, our study disclosed 63 of 76 alcoholic patients with hepatic lesions from slight fatty change to advanced portal cirrhosis These statistics may have to be qualified by the number of patients, the method of their selection for biopsy, and the interval from admission to biopsy Fatty liver is noted by other authors in needle biopsy and at autopsy as a frequent condition in acutely intoxicated patients [2,3,6] That portal cirrhosis occurs with a somewhat greater incidence among chronic alcoholics than among teetotalers has also been reported [6]

The biopsies in our patients could be arranged in a progression from slight fatty change through marked fatty change to portal cirrhosis which closely follows the development of portal cirrhosis seen in experimental animals and theorized for human beings In certain experiments, portal cirrhosis stems from fatty liver of sufficient degree and duration [6] Connor postulates three stages for Laennec's cirrhosis in human beings (1) fatty liver, (2) fatty liver with fibrosis (early fat cirrhosis), and (3)

cirrhosis with little or no fat [7 8] Fatty change and cirrhosis of the liver in alcoholic patients is complicated sometimes by acute or recurring hepatitis [9]

Because alcohol itself generally fails to produce cirrhosis experimentally and because a deficient diet generally succeeds, the consensus of opinion today is that fatty change and cirrhosis of the liver in alcoholic patients is brought about primarily by influence of nutritional deficiency which accompanies alcoholism rather than by sole direct effect of the alcohol [6] In our patients, histories of poor dietary intake for food elements and vitamins were consistently elicited Some authors still ascribe a basic role to alcohol itself in the pathogenesis of fatty liver and cirrhosis [7 8 10]

Why biopsies in 13 of our patients revealed no hepatic lesions remains a matter for speculation On the average, factors in these patients such as acute chronic alcoholism, dietary deficiency, and interval from admission to biopsy coincided with those in patients with abnormal biopsies In any of our patients we cannot exclude the possibility of alleviation of hepatic lesions through abstinence from alcohol, bed rest, and treatment with diet and other measures in the interval between admission to the hospital and biopsy

Answering the question, how may hepatic lesions in the alcoholic patient best be detected intravitam, we will consider the three diagnostic methods used in our study—clinical examination, hepatic function tests, and needle biopsy

Clinical examination was of limited value in detecting, with any regularity and precision, the extent or type of hepatic lesions Indeed, although we reviewed the clinical impressions of hepatic involvement charted on admission of our patients, we have not listed them in our results, nor have we attempted to correlate them with biopsy findings, for we feel that, except in the group of decompensated cirrhosis, such impressions were essentially guesses between fatty liver and Laennec's cirrhosis, based on the presence of a palpable liver in an alcoholic patient It is easy to see, therefore, why clinical examination was of limited value in detecting hepatic lesions The physician usually depended upon a palpable liver for his fundamental diagnostic criterion Hepatic lesions existed regardless of whether the liver was palpable In eight of 13 livers, described histologically "normal," the organ was palpable On the other hand, among 63 patients with hepatic lesions from slight fatty change to cirrhosis, the liver was not palpable in nine (two apparently atrophic cirrhosis) Fewer livers were "not palpable" in marked fatty change and in cirrhosis than in slight to moderate fatty change

Even with a palpable liver clinical distinction between fatty liver and cirrhosis was difficult Physical findings like palpable spleen, jaundice, ascites, spider nevi, and edema, especially when in combination, were associated, for the most part, with the palpable liver of cirrhosis, but certain cirrhotic patients were clinically compensated Further, some of the aforementioned findings are reported to occur in patients without advanced cirrhosis Such physical findings may denote hepatic functional insufficiency and need not necessarily mean irreversible cirrhotic changes

Although hepatic functions tests were more revealing of hepatic lesions than clinical examination, they also possessed definite limitations Results of function tests correlated fairly well with histologic findings in the group of livers we described "normal" In this group 10 per cent of the tests gave abnormal results, with three of ten results beyond the borderline range In the group with slight to marked fatty liver, 20 per cent of the tests gave abnormal results, of which 50 per cent were beyond the borderline range

In the group of livers with marked fatty change-cirrhosis and advanced portal cirrhosis, 50 per cent of the tests gave abnormal results, of which 74 to 80 per cent were beyond the borderline range From a functional standpoint marked fatty liver with cirrhosis came closer to advanced portal cirrhosis than to marked fatty liver without fibrosis In advanced portal cirrhosis, the compensated livers made up 40 per cent of the group and supplied 25 per cent of abnormal tests, of which 67 per cent gave results beyond borderline range The decompensated livers, composing 60 per cent of the group, supplied 75 per cent of abnormal tests, of which 83 per cent gave results beyond borderline range Combinations of tests were more dependable than single tests, since in many cases only certain tests were abnormal The more severe the hepatic lesions, the more frequent was the incidence of multiple positive tests per individual patient Lack of absolute correlation between function tests and hepatic lesions is well known and has been explained by reserve and regenerative power of liver, by the numerous independent hepatic functions, and by the type of lesions [11 12]

In fatty liver, cephalin flocculation and formol gel gests, hippuric acid synthesis, and bromsulfalein test furnished positive results more consistently than other tests In marked

fatty liver with cirrhosis and in advanced portal cirrhosis the most reliable tests were Van den Bergh, bromsulfalein, cephalin flocculation, and formol gel tests. Of less reliability were serum albumin determination, albumin-globulin ratio, prothrombin level, colloidal gold and thymol turbidity tests, and hippuric acid synthesis. Serum albumin slightly outranked the albumin-globulin ratio in number of abnormal results. Colloidal gold and thymol turbidity tests were positive only in the cirrhotic group. Alkaline phosphatase tended to exceed 10 units as jaundice increased.

In view of the diagnostic limitations of clinical examination and functions tests in our study, we feel that needle biopsy is the only method for detecting hepatic lesions in the alcoholic patient with regularity and precision. Needle biopsy demonstrates not only the type but also the degree of hepatic involvement. Thus, it offers valuable and challenging information for the treatment and prognosis. As Himsworth remarks, "The seriousness of hepatic disease in alcoholic patients is often not clinically obvious until the last stages. Puncture biopsy by allowing its appreciation at an earlier stage may enable a decisive influence to be brought to bear upon many members of the group while their illness is still curable." To certain objections against needle biopsy of the liver as a diagnostic procedure, we can make these comments. In our series of 80 alcoholic patients we encountered no serious complication from needle puncture. (Hazards reported in the literature comprise hemorrhage, infection, and perforation of viscus.) The objection that findings in a thin needle biopsy may not represent those in other parts of the liver does not hold in alcoholic patients because fatty liver and portal cirrhosis are diffuse processes. With a cooperative patient, experienced operator, and an adept technician, the number of unsatisfactory specimens should reach a minimum.

Prognostically, with repeated needle biopsy one can follow hepatic lesions in response to therapy or in progress under continued alcoholism. On these points our study presented no conclusive data. In biopsy of one moderate fatty liver five weeks after the first biopsy, the amount of fat was unchanged. Among three cirrhotic livers with biopsies three and one-half, four and one-half, and seven weeks after the first, two showed some decrease in fat, the cirrhosis was unaltered. Two patients with slight and moderate fatty liver and one patient with cirrhosis had readmissions for alcoholism twenty-two weeks, thirteen months, and one year, respectively, after the first biopsy when second specimens contained same amount of fat. Five of our patients died in the hospital, four in the cirrhotic group (ruptured esophageal varices, two, acute jaundice, one, tuberculous peritonitis and hematogenous tuberculosis, one), one with moderate fatty liver (lobar pneumonia). Two postmortem examinations of the liver confirmed the biopsy diagnosis of cirrhosis.

Of 12 "normal" livers stained for iron pigment, only two showed more than minimal amount. The cirrhotic livers had the greatest number with large quantities of iron pigment. In general, pigment in slight and moderate amount was distributed in parenchymal cells as fine blue granules. With increasing amounts, pigment became more prominent as denser aggregates in parenchymal cells and also in Kupfer cells, portobiliary spaces, and fibrous tissue between nodules. Iron pigment appeared first and most strikingly in peripheral zones. In two cirrhotic livers the iron pigmentation was of such degree that one was labeled "pigment cirrhosis" and the other was considered in relation to this entity. Repeated needle biopsy of the liver may prove a new method to study the pathogenesis of pigment cirrhosis and hemochromatosis. Gillman and Gillman, from their observations on the fatty liver of adult pellagrins, state that "the siderosis represents a profound disturbance in intracellular metabolism" and "is a good indicator of the chronicity of the malnutrition."[13,14] Besides iron pigment and bile pigment we saw an iron-free pigment which in certain sections was as apparent as the iron pigment. Similar pigment has been described by Gillman and Gillman.[13,14]

Summary

Needle biopsies of the liver were made on 80 alcoholic patients, nearly all of whom were in a state of acute intoxication on admission to the hospital. The hepatic findings fell into the following groups: Preserved ("normal") liver, fatty liver, fatty liver with cirrhosis, and portal cirrhosis. A correlation was attempted between the histologic picture in the various groups and the available function tests in each case. Seven patients had repeat biopsies. Stain for the presence of iron-containing pigment was done on 77 specimens of 72 patients.

We are indebted to Mrs. Victoria Coppola and Miss Dorothy Antkowiak for technical assistance.

Discussion

K. L Terplan, M D , *Buffalo* —To all of us who are called upon to give a diagnosis on minute particles of liver tissue obtained through a needle, the findings presented by Dr Sanes are impressive I believe Dr Sanes and his associates should be congratulated on the work accomplished, in which the corroboration of clinical data, including various liver function tests pointing to liver damage, by certain microscopic structural changes, is, perhaps, the most informative one, for we all know the limitations inherent in interpreting fatty changes in the liver, in general, and in these so-called "minute liver slivers, in particular It is fortunate that the material obtained by needle biopsy is taken from the lateral portions of the liver Here focal accumulation of fat involving numerous liver cells is usually not observed in otherwise not fatty livers This peculiar focal fatty change is, not uncommonly, close to the falciform ligament Whether or not slight or moderate fatty change in the biopsy material is reflecting actual liver damage might sometimes be difficult to state, but it is especially in these cases of chronic alcoholics in which any future information as to the progression of liver disease to cirrhosis and fatal outcome on the one hand, or possible recovery on the other hand, might be of great value The minute size of the material obtained by needle biopsy is, in itself, prohibitive of complete histologic analysis, including, in particular, various staining methods for fat Perhaps, in some instances, gelatin imbedding of the material could be tried for fat stains

From various reports in the literature, including extensive studies on postmortem material, it seems to be realized more and more that there is no diffuse storage of fat in otherwise normal livers The diffuse fatty changes (steatosis) seen in some chronic alcoholics is possibly reflecting similar nutritional deficiencies as those observed in some chronic infectious diseases as, for instance, tuberculosis

If I might digress from Dr Sanes's findings in chronic alcoholic patients for a moment, we found the needle biopsy very informative and a reliable diagnostic method in numerous instances of liver disease, especially in the differential diagnosis of icterus The diffuse hepatocellular damage, collapse of liver cells with ectasia of capillaries (red atrophy) on the one hand, and numerous bile thrombi within the not too impressively damaged liver cells on the other hand—these findings proved to be very reliable for the differential diagnosis of hepatitis and toxic dystrophy and obstructive jaundice The so-called inflammatory element might be just as conspicuous in acute and subacute dystrophic liver damage as in ascending cholongitis

---

FEWER PHYSICIANS GRADUATED IN 1949

The American Medical Association reported recently that the 1949 class of physicians was the smallest graduated in ten years, but that the incoming crop of freshman this fall is expected to be the largest on record The A.M A., making its annual report on medical education in the United States and Canada, said that 5,094 physicians were graduated in this country in June, compared with 5,543 the previous year The small number of graduates was attributed to the fact that the graduates started training in the last year of the war, when medical students were not granted deferment under selective service

However, the A.M A. said the expected enrollment of freshmen in American medical schools this fall is 6,900, the largest on record Last year's freshmen totaled 6,688

Of this year's graduates, 612 were women, the largest number in history The previous record was 392 in 1948 Canadian schools, the A.M A said, graduated 679 physicians this year, compared with 632 in 1948

THE TOXICOLOGY LABORATORY AND ITS IMPORTANCE TO THE COMMUNITY

NIELS C KLENDSHOJ, M D , and MILTON FELDSTEIN, B S ,* Buffalo, New York

(From the Toxicology Division, Department of Pathology, University of Buffalo School of Medicine)

FACILITIES for toxicologic investigations are inadequate throughout the United States as a whole Although many clinical laboratories are capable of performing a few selected routine determinations such as lead, arsenic, and barbiturates, only a few large centers possess laboratories sufficiently well staffed and equipped to handle full-scale toxicologic investigations It is truly amazing that American pathologists in general have been so disinterested and complacent about lack of access to toxicology laboratories We would not hesitate to state that a pathology service without a competent toxicologist is handicapped as much as any medical or surgical service would be without modern clinical laboratories

The long-recognized need for a toxicology laboratory in Buffalo resulted last year in the creation of a Division of Toxicology within the Department of Pathology of the University of Buffalo School of Medicine Inasmuch as the subject of toxicology is being brought to the fore throughout the country today, we thought that it might be of general interest to relate some of the considerations upon which we based the organization of our toxicology division and also to relate some of our experiences over a period of slightly more than a year since the laboratory began to function

When the establishment of the laboratory became a definite possibility, our primary consideration was to obtain an estimate of the magnitude and scope of the functions it would be required to carry out In order to do this, one of us spent two weeks as an observer in the toxicology department of the chief medical examiner's office in New York City The greatest part of the service of this laboratory consists of handling material submitted by the various medical examiners Because of the magnitude of this material, it represents a good cross section of what demands a toxicology laboratory should be able to meet From these observations we came to the conclusion that, although other laboratories would, of necessity, be operating on a smaller scale in regard to the number of determinations, they would be required to handle an equally extensive variety of problems That these expectations have been confirmed is shown by the fact that, out of a total of 187 cases handled, determinations were made for 27 different substances This means that a toxicology laboratory should serve a relatively large population, our estimate is that approximately one million people is preferable if its function is primarily to investigate cases submitted by hospital pathologists and medical examiners It is our opinion that laboratories established to serve smaller groups of people would have to fill other functions for the sake of economy and thus, in many cases, be forced to compromise on the quality of services available Furthermore, a laboratory needs to be of a certain size to offer opportunities for research We feel this is particularly important, not only because experience has shown that an investigative unit will maintain higher standards if it devotes part of its time to research, but also because there is a definite need for information about almost every branch of the work

The ideal place for a toxicology laboratory is a medical school, primarily because toxicology should be practiced in close cooperation with a teaching department of pathology wherever possible Such close relationship between pathology and toxicology may eventually form a good practical nucleus for the future development of a full-fledged department devoted to the teaching of forensic medicine Our toxicology laboratory is, as already mentioned, a division within the Department of Pathology of the University of Buffalo School of Medicine It serves as the official toxicology laboratory for the county medical examiner's office, and it is also associated with the Crime Detection Laboratory of the Buffalo City Police in a supplementary and advisory capacity Efforts are being made to develop working arrangements with the area hospitals and their pathologic laboratories, and, of course, our services can be engaged by any legitimate practitioner or official body with authority to request toxicologic investigations

It is not particularly difficult to point out the importance of a toxicology laboratory to the community as a whole A point that should be heavily stressed is the importance to the medical profession—general practitioners and specialists alike In spite of a natural distaste on the part of most physicians to testify in court cases, almost every physician in the course of his

* By invitation.

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Pathology and Clinical Pathology May 5 1949

practice must appear as an expert witness from time to time Many cases, with particular emphasis on those which come principally under the Workmen's Compensation Act, involve effects of exposure to poisonous substances The doctor's expert testimony too often must be based on purely clinical impressions, and we are sure that the doctor himself frequently feels that his testimony is not entirely expert Confirmative laboratory work by a competent toxicologist can supply data upon which the attending physician may base his testimony with greater assurance

We shall present some statistical figures illustrating the type of determinations which the toxicology laboratory has been requested to perform in the period between February 1, 1948, and March 15, 1949, which is a little more than the first year of operation During this period a total of 187 cases were investigated, of which 99 originated in the medical examiner's office These 99 cases represent most of the medical examiner's cases in which the county pathologist was requested to perform an autopsy This is not to be interpreted as suggesting that violent deaths in Buffalo are almost exclusively caused by those following in the footsteps of the famous Borgia, but it does indicate the medical examiner's interest in the state of sobriety of those meeting violent death, because brain and blood alcohol determinations were performed in 63 cases Thirty-five of these tests for alcohol were positive, suggesting the relative frequency with which cases investigated by the medical examiner meet death while under the influence of alcohol Relatively few blood alcohol determinations during life were performed This is not the place to discuss the merits of blood alcohol tests, but one instance may serve to illustrate the usefulness of the test under unusual circumstances

A plaintiff in a Workmen's Compensation action during a final hearing behaved in a manner which suggested severe intoxication, and the court suspended proceedings A blood alcohol determination, performed by the toxicology laboratory immediately after, established the fact that the plaintiff's blood was entirely free of alcohol and that his behavior had been due to illness

During the period under discussion, 21 tests for barbiturates in blood or central nervous tissue were performed, in which 10 tests were found to be positive From a purely clinical standpoint it may not be of major importance which one of the many commercially available brands of barbiturates were involved, but medicolegal considerations at times make it important to identify the actual barbiturate used In two specific cases we cooperated with the Federal Food and Drug Administration by identifying the actual barbiturates used, thus aiding this law enforcement agency in its efforts to check possible illegal distribution channels for barbiturates Complications in the determination of barbiturates arise from the prevailing custom of using combinations of short- and long-acting barbiturates A toxicology laboratory should be prepared to separate such mixtures of barbiturates and should also be able to identify each of the barbiturates available commercially

The laboratory performed 16 tests for carbon monoxide, of which 12 were positive Of course, quantitative tests for carbon monoxide are performed in many laboratories and do not present any special technical difficulties, but it is important to have available easily accessible facilities for quantitative determinations, because carbon monoxide poisoning is common and legal issues may often depend on promptly performed chemical tests For instance, we had a case of a workman who became ill while doing repair work on a chimney He was suspended from a scaffolding at a considerable height and fell to his death before help could reach him The workman was engaged by a contractor performing the repair work and was not employed by the owner of the industrial plant The owner and the contractor carried compensation insurance with two different insurance companies The immediate analysis of the blood of the deceased revealed a large degree of carbon monoxide saturation, and this finding was instrumental in fixing the financial responsibility

During the period mentioned above, we have been called upon to investigate poisoning with mercury, arsenic, and lead We have obtained positive tests for mercury in seven cases, for arsenic in six cases, and for lead in 22 cases Practically all the lead cases have involved action under the Workmen's Compensation Act

Our laboratory has performed quantitative determinations for silica on lung tissue in nine cases It is quite remarkable that, in these nine cases, only two were found to have less than 100 mg of silicon dioxide per 100 Gm of tissue, thus confirming in seven cases the suspicion of the pathologist that the fibrotic state of the lungs was due to silicosis

We have been able to confirm five cases suspected of morphine poisoning and two of atropine poisoning We have also investigated one case of suspected aconitine poisoning, but we were unable to determine the presence of this alkaloid Other cases investigated involved one instance of nitrite poisoning, one of borate poisoning, two iodide and one bromide poisonings In addition, two fatal cases of methyl bromide poisoning may be mentioned, one case involving chloral, one the accidental poisoning with methyl salicylate, and

two other cases of poisoning by ingested salicylates Altogether five tests were performed for cyanide, of which two were positive

Our services were engaged in one case in which a child died as the result of the substitution of pontocaine for procaine for cystoscopic purposes In this case an investigation by the proper authorities indicated all safeguards in the handling of the local anesthetic had been observed and that no mistake could have been made However, our laboratory demonstrated immediately that the solution used contained pontocaine instead of procaine and that the mistake in handling had occurred in spite of all precautions It is unfortunate that such accidents should ever happen, but even the best planned safeguards involving the human element are not infallible, and the services of a competent laboratory can at least aid in clarifying otherwise unexplainable events

It may be interesting to mention just in passing that our laboratory during the period under discussion performed, altogether, 764 individual tests and determinations This number of tests includes a great deal of work in 13 cases of unexplained deaths In these cases no particular reasons were advanced for suspicion of poisoning, and toxicologic work was supplementary to the general pathologic investigations in order to rule out the presence of poisons

We cannot state at present that we have very definite plans for the future development of our toxicology laboratory Unquestionably, the performance during the first year of operation and the general interest evinced by various institutions in our community assure development along lines already established We hope that there will be increasing cooperation between our laboratory and doctors and engineers interested in prevention of poisoning in our industrial plants Such teamwork as we visualize in this respect in the future may very well become an example of preventive medicine at its best

One may perhaps also think of the future on a broader scale than that strictly pertaining to benefits to the local community In particular, we have in mind the steadily expanding need for investigative work on the toxicology of new drugs Federal Food and Drug Laws enacted some years ago have contributed immensely to the safe use of new therapeutic remedies as well as control of potency and purity of drugs The cooperative spirit between the Federal Food and Drug administration and the pharmaceutical industry has contributed to recognized methods for toxicologic investigations, and it is very desirable on the part of government agencies as well as pharmaceutical houses to have independent toxicologic facilities available We feel that cooperative arrangements between toxicology, pathology, and pharmacology departments in medical schools are ideally suit for such purposes

This paper would be incomplete without a word of appreciation of the advice in respect to the operation of a toxicology laboratory extended from the office of the chief medical examiner in New York City The cooperation and help given by Dr Thomas A Gonzales, chief medical examiner, and Dr Alexander O Gettler, city toxicologist, as well as members of their staff, are sincerely appreciated in Buffalo

Summary

We have described briefly some of the preliminary considerations upon which we based the establishment of the Toxicology Division within the Department of Pathology in the University of Buffalo School of Medicine We have also related some of our experiences during a period of slightly more than a year of operation of this new division

Discussion

Samuel Sanes, M D , *Buffalo* —Discussing this paper as pathologist in the Medical Examiner's Office of Erie County, I wish to express gratitude to Dr Klendshoj and Mr Feldstein for the help which they have given us in the solution of our cases, particularly those which were autopsied Toxicologic investigations are indispensable in medicolegal work From the time the toxicology laboratory went into operation until today, we submitted material in 75 per cent of our autopsies for study In 15 to 20 per cent of our autopsies, poisoning was the primary or a chief cause of death Toxicologic information was of great value also in other cases where poison played a contributory or incidental part The toxicology laboratory gives us not only a qualitative report, but also a quantitative analysis, further, it determines the specific agent in a group like the barbiturates Such information is of special importance to us

I should like to cite types of cases with examples in which the medicolegal pathologist depends upon the toxicologic laboratory for help

1 Those cases in which autopsy is negative for organic findings An elderly man is found dead in his hotel room The toxicologist proves morphine in gastric contents and tissue Morphine is also demonstrated in the contents of a bottle picked up by police in the bathroom

2 Those cases in which autopsy shows organic findings for which a cause must be determined An elderly woman with gastrointestinal complaints dies shortly after admission to the hospital in shock before a medical workup There is no definite clinical diagnosis At autopsy, ulcerative gastritis and colitis suggest heavy metal poisoning The toxicologic report is positive for mercury in gastric contents, viscera, and urine Bacteriologic cultures are negative

3 Those cases in which autopsy has to set liability for industrial compensation The case of

carbon monoxide poisoning mentioned is a good example.

4. Those cases in which autopsy presents obvious organic findings to explain the immediate cause of death, but in which toxicologic examination explains behavior of the person before death or circumstances leading to the cause of death. A truck driver is found ill in his cab; he dies later of fractured skull and intracranial injury. Police account for practically all his activities. Blood sample shows an increased carbon monoxide saturation. Investigation of the truck reveals an exhaust pipe communicating with the cab through a defective floor.

5. Those cases such as homicides and hit-and-run accidents in which at autopsy alcohol determinations are obligatory.

6. Those cases in which at autopsy it is desired to complete the chain of evidence for homicide. A mother strangles her two small children allegedly after giving them some sleeping pills. Toxicologic report is positive for a particular member of the barbiturate group, the exact source of which can be traced.

7. Those cases in which public interest is aroused. Two women die within a short time of each other from acute abdominal complaints. Both lived on a city dump. Autopsies disclose no organic findings to explain death. Newspapers and radio stations publicize the cases, even with editorial comment. Are the deaths related? Did the women die of rat poison used by a municipal department on the city dump? Did they die from food poisoning after eating discarded food or from acute food infection? Did they die from methyl alcohol poisoning? Toxicologic examination is positive for methyl alcohol in both women. Various bacteriologic studies are negative.

8. Those cases in which at autopsy it is essential to exclude poisoning. Rumors spread that a person whose death was certified as due to natural causes was really a suicide from poisoning. Autopsy after disinterment confirms the organic cause of death signed on the death certificate. Complete toxicologic examination reveals no poisons in the tissues.

Abraham W. Freireich, M.D., *Malverne*.—The paper by Dr. Klendshoj and Mr. Feldstein presents a somewhat different slant on toxicologic problems from that which we have in Nassau County. One of the big problems that confronts a group seeking to improve their standards of medicolegal investigation

TABLE 1.—MEDICAL EXAMINER'S SYSTEM—NASSAU COUNTY

Year	Number of Cases	Toxicologic Examinations
1938	546	196

is the expense in providing the space and equipment for toxicologic examinations. It is certainly desirable to provide fully equipped laboratories for all types of toxicologic studies as well as for research. However, the greater need at the present time is to improve the caliber of the routine medicolegal investigation. I have in mind the comparative merits of the medical examiner's system over the coroner's system. Our experience in Nassau County may be of interest to you.

On January 1, 1938, there was established a medical examiner's office in Nassau County, replacing the old coroner's system. Dr. Theodore J. Curphey, who was at that time pathologist at Meadowbrook Hospital, was appointed the chief medical examiner. Our office was established at Meadowbrook Hospital, and the existing morgue facilities and autopsy room, as well as the clinical laboratories, were made available to us. With the addition of a modest amount of equipment, we began to perform toxicologic studies as part of the routine investigation of cases coming under the jurisdiction of the medical examiner. Table 1 indicates the number of examinations performed each year from 1938 to 1948, inclusive. It also lists the total number of cases investigated by the medical examiner. Table 2 is a summary of the types of examinations performed in 1948. As can be seen, a total of 303 examinations were done. Almost half of these consisted of determinations for the presence of alcohol in either the brain, blood, or spinal fluid, the greatest portion being in the brain. The breakdown as to the positive cases is indicated. Seventy examinations were done for the presence of carbon monoxide in the blood. A goodly number of these examinations were performed on bloods removed from a cadaver by means of a large needle inserted directly into the heart, eliminating the necessity for a complete autopsy. This was done when the evidence at the scene and the external examination of the body gave good presumptive evidence that carbon monoxide

was the cause of death The remainder of the examinations consisted of a small number of tests for barbiturates, mercury, cyanide, arsenic, fluorides, paraldehyde, and phosphorus and for drownings The classification, "General Unknown," is made on those cases where the autopsy fails to reveal an adequate cause of death and in which poison may have been the factor but no definite lead as to the specific poison is obtained In this category, of course, a *larger number of tests has to be performed* Of the 25 cases, seven resulted in the finding of a poison sufficient in quantity to be considered the cause of death Five of these were barbiturates, one salicylates, and one fluoride

My purpose in presenting these facts is to emphasize that the major portion of work that a toxicologic laboratory may be called upon to perform consists of the more easily determined substances and for which no very elaborate equipment is necessary It is true that one would prefer to have such apparatus as spectrographs, spectrophotometers, and possibly other physical equipment which makes exact analysis of poisons more easily determined, but the expense of such equipment and the comparatively small number of uses such equipment would have in a small community makes them a luxury which most of us cannot afford Our experience in a county of roughly 500,000 population has been such that we have been able to perform with a reasonable amount of adequacy the requests for aid to the pathologist and to the medical examiner's office and to the district attorney's office in their investigations.

The problem, to my mind, is more that of training sufficient personnel to take over the duties of *toxicologic examinations rather than that of* physical equipment An individual trained in the science of toxicology will have the judgment to decide when he can rely on the results of the tests performed with his equipment and when he has to seek further aid

To that end there can be established a few centers throughout the State, like the one in New York City, with the finer equipment for more exact determinations which will be available to all the jurisdictions in their area.

In summary I wish to stress that the problem of personnel is greater than that of physical equipment, that duplication of infrequently used expensive equipment is not necessary, and, finally, a suggestion has been made as to how that can be done.

EMBALMING

It will certainly surprise most people to know that the number of subjects prepared for burial by embalming has increased in Great Britain from almost zero to one-fifth of the death rate in the past fifteen years The advantages of the practice are first as a hygienic method of dealing with the body awaiting disposal, especially if delay is necessary or anticipated, and then in its psychologic effect on the bereaved and the simplification made possible in the funeral arrangements The embalmer is concerned with appearance equally as much as with sterilization, and the technics include closing of the eyes and mouth, hairdressing, shaving, positioning, dressing, and "make-up" One result is that the deceased person can be left as though peacefully sleeping in bed until the actual time of the funeral, with the resultant avoidance of "all the gruesome accoutrements of the death chamber" An obvious incidence of the value of embalming is a death at sea in which it is desired for any reason to bring the body home for disposal There are also indications in the medicolegal field Lear quotes a rather gruesome incident in which embalming helped to meet a difficult situation During the war so many patients died *from influenza in* a London hospital that the bodies could not be accommodated in a refrigerator, and during the night rodents came into the mortuary and disfigured the faces of many of the bodies, to avoid distress upon relatives, the bodies were embalmed, and then by means of "derma surgery" it was possible to rebuild the damaged tissues so that no evidence of disfigurement could be observed

The process of embalming is, in broad terms, the complete irrigation of the vascular system by a disinfecting solution injected into one or more of the main arteries, the blood being simultaneously drained from one or more of the main veins The solution is basically one of formalin, glycerin, and borax with coloring matter to restore the natural complexion of the tissues Satisfactory distribution removes all traces of cyanosis and hypostasis, and the massage of the exposed parts during the course of the injection results in the complete restoration of the natural contours Normal or abnormal body fluids are removed by aspiration, and parts or substances not receiving the supply of embalming cannot go in the course of the arterial injections, as for example fecal matter in the alimentary tract or special diseased areas, are cared for by a direct injection of a concentrated embalming chemical. There can be little doubt that embalming is a highly *developed technic and its value needs no stressing — Current Medical Digest, July, 1949*

APPLICATION OF SPONGE BIOPSY FOR CANCER DIAGNOSIS IN OFFICE PRACTICE

SIDNEY A GLADSTONE, M D , New York City

(From the Department of Pathology, New York Polyclinic Medical School and Hospital)

AN IMPORTANT spearhead in the present concerted attack on the cancer problem is the development and improvement of simple, reliable methods of diagnosis The key to cancer cure, in many instances, lies in early diagnosis at a stage of the disease when signs and symptoms may be slight if not entirely absent The visual acuity of the physician in the examination of all accessible body surfaces which may be the site of cancer could be multiplied several hundred times if it were possible to focus the high powers of the microscope on all these surfaces without significant disturbance to the patient The medical practitioner occupies a strategic position in encouraging and requesting the microscopic examination of all early accessible ulcerative lesions of skin and mucous membranes to determine the presence or absence of cancer, especially since that determination may now be made by a simple procedure which avoids the hazards of pain, hemorrhage, and infection This procedure is the recently introduced method of sponge biopsy for the diagnosis of cancer [1–5]

Technic

Sponge biopsy for the diagnosis of cancer in accessible areas is performed by firmly rubbing a suitable sponge over an ulcer or mucosal surface The sponge will absorb tissue juice, suspended cells, and particles of tissue The sponge with its absorbed contents is then placed in a small bottle of 10 per cent formalin for fixation, after which, in the routine manner, it is embedded in paraffin, cut by microtome, and stained with hematoxylin and eosin prior to examination by a pathologist The microscopic sections will show the network of the sponge, on the surfaces and in the interstices of which will be seen the coagulum of tissue fluid with suspended cells and tissue particles If the sponge has been rubbed in contact with a cancer, one will find cancer cells, singly and in groups, as well as particles of cancer tissue with their characteristic cytologic and histologic abnormalities

We have worked mostly with two types of sponge, one gelatin (Gelfoam Number 12, The Upjohn Company, Kalamazoo 99, Michigan), the other cellulose (Onkosponge Number 1, Histomed, Incorporated, Paterson 1, New Jersey) Both these sponges have good absorbing power and are easily cut by microtome after embedding in paraffin The cellulose sponge has greater tensile strength, is less likely to tear, keeps its form better after compression and wetting, and has slightly more abrasive power, thus facilitating the removal and absorption of tissue particles from granulating surfaces It is interesting that these sponges are derivatives of connective tissue, animal and vegetable, respectively In order to facilitate proper application of the sponge, we have introduced a special sponge biopsy forceps (Histomed, Incorporated, Paterson 1, New Jersey) This instrument is equipped with a narrow, flat, diamond-shaped surface extending beyond the point of seizure of the sponge to provide support from behind and permit firm pressure as the sponge is rubbed over the ulcer or mucosal surface to be examined (Fig 1)

The success of the method depends on the transfer of cancerous material from the lesion to the sponge and the microscopic demonstration of that material in the stained sections Our experience to date indicates that in most cases no special precautions are needed for the successful application of the method To insure the best results in the highest percentage of cases, however, the adherence to a few simple technical suggestions will prove helpful

First, a clear visualization of the lesion is essential This presents no difficulty in ulcerations of the skin, cervix, mouth, etc In the

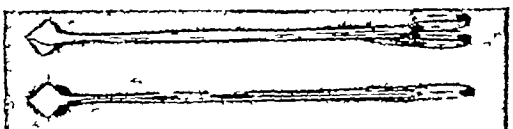

FIG 1 At the top is the special sponge biopsy forceps showing diamond-shaped plate behind the sponge In the middle is the same seen from the opposite side, showing the square sponge and the corrugations on the short arm to facilitate scraping of hard or granulomatus surfaces such as skin, lips, mouth, rectum, etc At the bottom is the long narrow uterine forceps with triangular sponge for insertion into lower portion of cervical canal

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Pathology and Clinical Pathology May 4 1949

rectum or rectosigmoid, however, good illumination and careful cleansing of the bowel by previous enema or by wiping with several cotton gauze sponges are important In general, the diagnostic sponge should be rubbed over the base of an ulcer and especially around its margins near the healthy surrounding tissue If the lesion is high in the rectum and its outlines are seen with difficulty, it is best to use three or four separate pieces of sponge, each rubbed firmly over the entire ulcerated or suspicious area Second, a chronic ulcerating lesion is usually covered with a varying amount of granulation tissue, necrotic tissue, and inflammatory exudate Such material is of no help in the diagnosis of cancer Accordingly, in an occasional case where an excess of such material covers the surface of the lesion, it should be firmly wiped with dry cotton gauze to remove the superficial grayish-white dead tissue, thus exposing the underlying living pinkish tissue, before the application of the diagnostic sponge Third, one should inspect the sponge after its application A sponge rubbed over an ulcer should be discolored to some extent by the absorbed material If no discoloration is seen, rub the sponge more firmly, and then turn the sponge over and rub the other side against the tissue to be examined When both surfaces of the sponge have thus absorbed tissue elements, even if these are not visible to the naked eye, the technician will not be able to make the mistake of cutting sections from the wrong side In general, a sponge which has been properly applied will be well soaked with tissue juice and suspended viable cells and tissue particles

Sponge biopsy of the cervix uteri requires two or three separate pieces of sponge One flat square, approximately 1 0 by 1 0 by 0 2 cm , is held in the special sponge forceps and is rubbed firmly over the entire surface of the lips of the cervix and the external os The second piece, triangular in shape, is made by cutting one of the above squares diagonally This piece is held at the end of a long narrow uterine forceps and is then inserted gently into the cervical canal for a distance of 0 5 to 1 0 cm , depending on the patency of the cervix (Fig 1) The sponge forceps is then rotated on its long axis, pressing the sponge against the mucous membranes of the lower cervical canal, the os, and the adjacent lips Both triangular pieces should thus be used If an ulcerative lesion is seen on the cervix, an additional piece of sponge should be rubbed on the ulcer, especially near the margins Sponges from a single area, such as the cervix, may all be placed in the same small formalin bottle

The tissue technician depends on the discoloration of the sponge as a guide in selecting the sponge surface to be sectioned The technician will cut sections from the sponge surface which has come into most intimate contact with the lesion, as indicated by the amount of discoloration and the presence of adherent mucoid or particulate matter If tiny free particles are seen in the formalin bottle, these particles should be processed along with the sponge and should be placed in contact with the sponge surface to be cut before embedding This may be accomplished by placing the particles in the melted paraffin and then covering them with the sponge The sections taken from the immediate surface of the paraffin block should be mounted Deeper sections may also be taken

The pathologist can quickly familiarize himself with the findings in sponge biopsy by rubbing sponges as described above over fresh tumors immediately after removal from the patient Sections from such sponges will demonstrate the ease with which cancerous material may be absorbed by a suitable sponge and demonstrated by microscopic examination

General Results of Sponge Biopsy

In a previous report we have presented the results of sponge biopsy in 280 cases, in 110 cases additional tissue for comparative study was made available by surgical biopsy, surgical specimen, or postmortem examination [3] That series included six cases of cancer of the cervix uteri, nine cases of adenocarcinoma of the rectum, three cases of skin cancer, and five cases of cancer of the vocal cords and bronchi "In these 23 cases of proved cancer, sponge biopsy results were positive in 19, presumptive positive in three, suspected positive in one The sponge was applied in these 23 cases by 12 different physicians, several of whom were not aware of the simple technical requirements elaborated during the course of this study In one of our cases of cancer of the rectum, the surgical biopsy was negative, sponge biopsy was positive Of the six cases of cancer of the cervix, two were completely asymptomatic" [3] On the basis of the comparative findings in the controlled series of 110 cases, it was concluded that "with respect to accuracy and reliability of results, the method of sponge biopsy closely approximates that of surgical biopsy"

Sponge Biopsy in Office Practice

In a series of 75 sponge biopsies performed by private physicians in their office and sent to us for examination, four cases of cancer were found These include one case of early carcinoma of the cervix, one advanced carcinoma of the cervix, one cancer of the rectosigmoid, and one cancer of the skin Brief summaries of these positive

FIG 2 Sponge biopsy of early carcinoma of cervix (Case 1) Note the particle of cancer tissue made up of large cells, with large, darkly staining nuclei showing marked variability in size and shape The dark solid bands of varying thickness are the gelatin framework of the sponge (440 ×)

cases are presented Two cases from our clinics are added to illustrate other types of carcinoma

Case 1—D S was a forty-eight-year-old white woman whose vague complaints were thought to be menopausal in origin and who accordingly was referred to a gynecologist for possible endocrine therapy There was no irregular bleeding or spotting A sponge biopsy of the cervix, which on inspection appeared quite normal, was included as part of the routine pelvic examination The sponge biopsy showed epidermoid carcinoma (Fig 2) This was confirmed by surgical biopsy, and a panhysterectomy was performed Examination of the specimen showed early superficial carcinoma of the cervix with one area of invasion 0 8 cm. in greatest diameter

Case 2—F F was a fifty-year-old white woman whose menstrual periods were regular until two months previously when bleeding began and continued to the present A sponge biopsy showed an

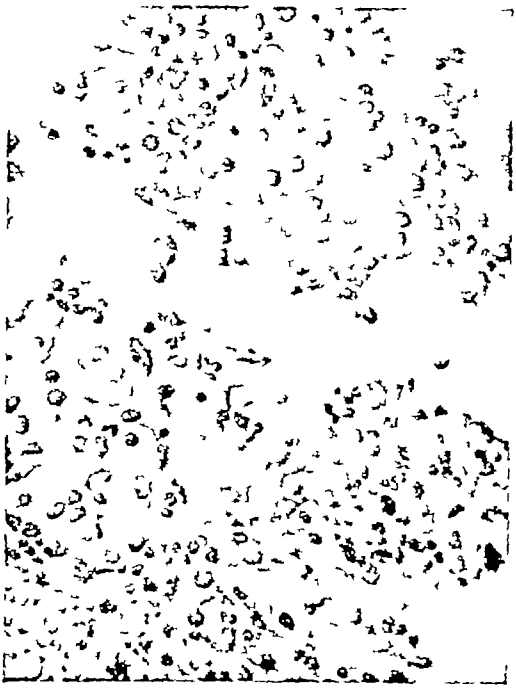

FIG 3 Sponge biopsy of advanced carcinoma of cervix (Case 2) The tumor cell nuclei are large, darkly staining, irregular, mostly round and oval, vary markedly in size The tissue is more anaplastic, showing less resemblance to stratified epithelium than does the tissue of the preceding case (440 ×)

abundance of blood and scattered particles of tissue diagnosed as epidermoid carcinoma (Fig 3) A surgical biopsy was performed shortly thereafter and reported as carcinoma of the cervix, grade 3

Case 3—J M was a thirty-eight-year-old white man who gave a one-year history of diarrhea and rectal bleeding A surgical biopsy done elsewhere showed "normal rectal mucosa, muscle wall, apparently polypoid tissue" The patient was referred to the office of one of our proctologists who saw a lesion in the rectosigmoid which appeared so friable that he preferred not to excise any significant amount of tissue because of possible perforation of the bowel wall He accordingly did a sponge biopsy The sponge biopsy showed numerous particles of tissue characteristic of adenocarcinoma of the large bowel (Fig 4)

Case 4—S S was a fifty-eight-year-old white woman complaining of a sore behind the left ear which did not heal despite continued treatment by a dermatologist The family doctor performed a sponge biopsy which showed small particles of tissue made up of large darkly staining anaplastic cells showing considerable variation in size and shape (Fig 5) This was diagnosed as carcinoma and, because of a history of a breast lesion three years previously was interpreted as probably metastatic

FIG 4 Sponge biopsy of adenocarcinoma of rectosigmoid (Case 3) The darkly staining atypical columnar cells are crowded together in irregular glandlike pattern and in solid masses Abundant blood is also present

FIG 5 Sponge biopsy of small carcinomatous ulcer behind the ear, metastatic from breast carcinoma removed three years previously (Case 4) Note the particle of cancer tissue with characteristic cell nuclei, large, darkly staining, round, oval, and irregular, varying in size and shape (440 ×)

from the breast A surgical biopsy of the skin lesion showed clumps of tumor cells in the subcutaneous tissue and lymphatic channels such as one sees in breast carcinoma, metastatic in the skin

Case 5 —H Q was a fifty-four-year-old white man seen in our dental clinic complaining of a "soreness" in the mouth of three months duration Examination showed an ulcerated area 1 cm in diameter in the left cheek behind the molars A sponge biopsy was performed and showed epidermoid carcinoma (Fig 6) This was subsequently confirmed by surgical biopsy

Case 6 —W S was a fifty-year-old white man who came to our nose and throat clinic complaining of soreness of throat of three months duration Physical examination showed a swelling on the right side of the nasopharynx Sponge biopsy showed particles of tissue made up of large atypical anaplastic cells, diagnosed as "carcinoma, probably lymphoepithelioma" (Fig 7) The surgical biopsy performed later showed lymphoepithelioma

Comment

The value of a diagnostic procedure varies directly with the importance and reliability of the information it reveals and inversely with the costs of the procedure, measured as cost to the physician in terms of time, effort, and requisite skill, and cost to the patient in terms of anxiety, pain, personal danger, and financial expenditure. A comparison of the method of surgical biopsy, which has been the standard method in the clinical diagnosis of cancer for two generations, with the method of sponge biopsy in respect to the several factors enumerated above may be useful to the physician in helping him to utilize each to its fullest possibility The importance of the diagnosis by either method needs no statement beyond the fact that, performed early, it may lead to complete cure, performed late, it is tantamount to an obituary notice As to reliability of the results, assuming that both methods are applicable and properly performed, our studies to date indicate that positive results are equally reliable with both methods, that an occasional false negative is possible with either method, and that doubtful results may be encountered more frequently with sponge biopsy

FIG 6 Sponge biopsy of epidermoid carcinoma of mouth behind molars (Case 5) Note comparatively large piece of tumor tissue made up of atypical stratified epithelial cells showing atypism and tendency to concentric pearl formation Adjacent is seen the irregular linear structure of the cellulose sponge (100 ×)

FIG 7 Sponge biopsy of carcinoma—lymphoepithelioma of nasopharynx (Case 6) A particle of tumor tissue is seen to consist of cells with large darkly staining irregular nuclei, showing considerable variation in size and shape (440 ×)

because of the comparative paucity of tissue available for examination

With respect to the costs to the physician in terms of time, effort, and requisite skill, the method of sponge biopsy is distinctly superior With respect to costs to the patient, i e, the anxiety, pain, and personal danger of a surgical biopsy which involves a minor surgical operation sometimes requiring hospitalization, the method of sponge biopsy, which is a simple office procedure, is certainly preferable With respect to financial cost, the advantage again lies with sponge biopsy A useful rule of procedure would be to obtain the diagnosis by sponge biopsy if possible and obtain it early If the findings do not fit in with the clinical picture, repeat the test, or use surgical biopsy to obtain more tissue for examination A consultation with the pathologist in the occasional doubtful or difficult case may save a great deal of time and effort

Statistically, most of the ulcers seen in the office are benign rather than malignant In malignant cases, surgical biopsy is a trifling procedure compared to the seriousness of the disease In many benign cases, surgical biopsy is a weighty procedure compared to the trivial nature of the disease and may cause more disturbance than the disease itself A simple and reliable method is required not only to diagnose malignancy, but also to demonstrate its absence in the large number of benign ulcerative lesions which simulate cancer and require microscopic examination In that category, the method of sponge biopsy has shown considerable promise

Several practical advantages of sponge biopsy become apparent in a consideration of the six cases briefly summarized above In Case 1, there was no evidence pointing to disease of the cervix, yet sponge biopsy revealed a carcinoma at that site A similar case from our clinic had previously been seen A confirmatory surgical biopsy prior to operation was considered desirable The cervix, however, appeared normal, and the problem of selecting a site for the biopsy arose In a recent study on the anatomic distribution of early superficial carcinoma of the cervix, Foote and Stewart found that a single piece of tissue taken from the most likely site will miss half the lesions [4] Several pieces are necessary In the present case the surgeon curetted the entire mucoepithelial ring at the

external os The tissue showed superficial carcinoma, with little invasiveness Taken alone, it might have been difficult to diagnose The previous sponge biopsy, however, had included very characteristic particles of cancer tissue obtained from the invasive portion of the tumor on the cervical lip, about 1 cm from the os, not detectable on visual inspection and completely missed by the biopsy scalpel The advantage of the sponge, therefore, is its ability to cover the entire surface of the lips of the cervix Early superficial cancer is soft, cellular, and friable, and particles of cancer tissue are easily detached and absorbed in the sponge which is firmly rubbed over the cervix The simplicity of this procedure and the important information it imparts would commend it as a routine test as part of the pelvic examination of any woman past thirty years of age

In Case 2, when the abnormal bleeding started, the disease was already far advanced Carcinoma of the cervix is a slowly developing disease, probably spread over several years Bleeding is a late sign resulting from extensive tumor growth and tissue destruction At this stage, treatment is likely to be costly, protracted, and ineffectual The time to treat cancer of the cervix is before extensive invasion and tissue destruction have taken place This can be done only by the early detection of the disease, which may be accomplished by sponge biopsy, by the use of cytologic studies of cervical secretions, by the examination of tissue scrapings, curettings, etc Of the several methods mentioned, the method of sponge biopsy appears to be the only one that detaches for examination tissue particles from the entire surface of the cervical lips and adjacent cervical canal and with a minimum of trauma at that

In Case 3, diarrhea and rectal bleeding were present in a man of thirty-eight for one year before the presence of cancer was demonstrated A previous attempt by surgical biopsy had failed Sponge biopsy made the diagnosis We have another similar case in our comparatively short series of rectal cases (about 15) Since the sponge rubbed over a rectal ulcer will pick up many tiny tissue fragments from different parts of the lesion, the chance of missing a malignancy, if present, is greatly reduced Furthermore, the hazard of possible hemorrhage following surgical biopsy in rectal ulcers is significant and may be avoided by the use of sponge biopsy In many cases the clinical and roentgen ray findings point to rectal or sigmoidal carcinoma, and tissue confirmation is desired prior to extensive operation In such instances, sponge biopsy is preferable by far to surgical biopsy

In Case 4, a small ulcer behind the ear in a woman of fifty-eight was treated by a dermatologist without success The history of a previous breast tumor pointed to a possible metastatic lesion This was found by sponge biopsy and confirmed by surgical biopsy

In Case 5, our dental surgeon showed us the ulcer in the mouth of this patient The dentist pointed out that a surgical biopsy would require local or general anesthesia Since the ulcer was obviously infected, local infiltrating anesthesia seemed undesirable Accordingly, a general anesthetic would be necessary We recommended the avoidance of these difficulties by the use of sponge biopsy This showed epidermoid carcinoma, later confirmed by surgical biopsy

In Case 6, a fifty-year-old man had a sore throat of three months duration and showed a swelling on the right side of the nasopharynx. A sponge biopsy gave a prompt diagnosis of "carcinoma, probably lymphoepithelioma," which was confirmed by surgical biopsy

The use of surgical biopsy is often postponed by the objections and delaying action of the patient or by the unwillingness of the physician to use a procedure which may disturb the patient more than the disease In a high percentage of cases, these difficulties can be resolved by the use of sponge biopsy

Summary and Conclusions

Sponge biopsy is a method of collecting tissue from an ulcerating or mucosal surface suspected of being cancerous The sponge firmly rubbed over the surface of the lesion will absorb tissue juice, suspended cells, and tiny dislodged particles of tissue Sponge and absorbed material are fixed in formalin, embedded in paraffin, cut by microtome, and stained by hematoxylin and eosin prior to microscopic examination by a pathologist The method is applicable to the diagnosis of cancer of the cervix uteri, rectum and rectosigmoid, skin, mouth, pharynx, etc On the basis of parallel determinations it has been found that, with respect to accuracy and reliability, the method of sponge biopsy closely approximates that of surgical biopsy Because of the simplicity of the technic, the reliability of the results, and the absence of pain, hemorrhage, or possible infection, the method of sponge biopsy commends itself as a useful office procedure

THE USE OF DICUMAROL IN ACUTE MYOCARDIAL INFARCTION

SEYMOUR L FRANK, M D , New York City

(From the Medical Service of the Bronx Hospital)

PERIPHERAL and pulmonary embolism still remain as dreaded complications of acute coronary occlusion with myocardial infarction Fairly frequently, these phenomena are directly responsible for the death of a patient whose recovery would otherwise be assured The problem of minimizing the occurrence of fatal complications has presented a challenge to the clinician which, until recently, more often than not could not be met successfully

Anticoagulants are used in the management of acute coronary thrombosis with myocardial infarction with four principal objectives in mind

1 To prevent the formation of intracardiac mural thrombi

2 To prevent pulmonary embolism from arising from thrombophlebitis

3 To prevent the extension of the thrombus, either proximally or distally to the original site of occlusion

4 To prevent the further development of thromboses in arteriosclerotic peripheral arteries

When interest in the anticoagulants became apparent, many physicians were still reluctant to employ them in the treatment of acute coronary thrombosis They felt that, since coronary occlusion is sometimes precipitated by subintimal hemorrhage into an atheromatous placque, the anticoagulants might, in those cases, play an adverse role Later evidence, however, showed this to occur in very few instances of coronary artery occlusion

Although the exact mode of action of Dicumarol is unknown, evidence seems to favor the concept that it inhibits the formation of prothrombin at its source This inhibition of the formation of prothrombin varies in different individuals, since it was found that identical doses administered by mouth to different persons produced variable effects on the prothrombin time Absorption and renal excretion may be important in influencing the effect of the drug on prothrombin Less than 5 per cent of patients appear to be resistant to Dicumarol In some, inadequate absorption may be the cause of this resistance, and larger and more frequent doses may be necessary On the other hand, patients are seen who are sensitive to Dicumarol and whose concentration of prothrombin in the blood may fall to critical levels after the first few doses These are the cases that may develop bleeding

Applying the knowledge of the value of Dicumarol in the treatment of peripheral thrombosis and embolism, a clinical study of the use of Dicumarol in intracardiac thrombosis as a result of acute coronary occlusion was undertaken at the Bronx Hospital Although only 32 cases are reported, it is felt that this series, together with others now appearing in the literature, will help to confirm the value of Dicumarol in reducing thromboembolic phenomena and mortality in acute myocardial infarction

Procedure

No case was considered unless it met all the criteria for diagnosis—clinical history and laboratory and electrocardiographic evidence of acute infarction There were many more that clinically presented this diagnosis, but failure of the electrocardiogram to confirm this impression excluded them from the series

Daily prothrombin determinations were made according to the method described by Quick.[1] The routine administration of Dicumarol was as follows On admission the patient had a prothrombin determination and a blood typing, the latter a routine procedure on all patients receiving anticoagulant therapy An initial dose of 300 mg of Dicumarol was given orally, followed by 200 mg the second day and 100 mg daily thereafter until the prothrombin level reached 20 per cent of normal The prothrombin level was kept as close to 20 per cent of normal as was possible If the level fell below 20 per cent, no Dicumarol was given When the level reached 20 per cent, in most cases 50 to 100 mg of Dicumarol given every other day aided in maintaining the level at this optimum point If there was any evidence of Dicumarol overdosage—gross hematuria, epistaxis, melena, etc —the drug was promptly discontinued and 72 mg of vitamin K given slowly intravenously and repeated in four hours if necessary If bleeding persisted, a transfusion of whole blood was given This procedure usually controlled whatever bleeding had ensued Should it be necessary, repeated transfusions can be given When bleeding had ceased, Dicumarol therapy was reinstituted with the critical level now raised to the point at which no bleeding had occurred

The patients were kept on anticoagulant therapy until they became ambulatory—in most cases at least thirty days At this point the drug was discontinued

Results

Of the 32 cases treated with Dicumarol, three died (9 4 per cent) One of these, a seventy-two-year-old man with a history of two previous infarctions, had been started on Dicumarol four days after admission On the tenth hospital day he suddenly developed acute left ventricular failure and expired His prothrombin level at time of death was 25 per cent of normal The second death occurred in a fifty-five-year-old man who had been admitted in a critical condition He was improving until there was a recurrence of dyspnea, orthopnea, and cyanosis on the fourteenth hospital day He died six days later, twenty days after admission His prothrombin level was 25 per cent of normal. The third fatality occurred in a sixty-eight-year-old woman who was showing marked clinical improvement until the ninth hospital day when, while turning in bed, she suddenly gasped for breath and expired At the time of death her prothrombin level was 45 per cent of normal In the latter two cases, the coronary episode was the initial one for both patients Unfortunately, permission for postmortem examination was not obtained in any of the three deaths, but the clinical impression as to cause of death was that of embolism.

The majority of the patients treated were in the sixty to sixty-nine year age group Of the others, the youngest was thirty-three and the oldest eighty-one years The latter developed an incarcerated femoral hernia (left) on the thirteenth hospital day, was given vitamin K intravenously preoperatively, and operated upon under local 1 per cent novocaine anesthesia Postoperatively he was continued on Dicumarol and left the hospital in good condition Of the 11 women and 21 men in the series, three, including one of the fatalities, had experienced previous myocardial infarctions

The electrocardiograms revealed eight posterior wall infarcts, 22 anterior wall, one posterolateral, and one lateral wall

The duration of Dicumarol therapy was approximately thirty days in most cases, with a minimum of nineteen and a maximum of fifty-eight days The average amount of Dicumarol given during the period of treatment was 1,750 mg, a minimum of 1,050 mg (nineteen days) and a maximum of 2,850 mg (fifty-eight days)

Two patients developed mild gross hematuria which was promptly controlled by cessation of the drug and intravenous administration of vitamin K.

Except for what was assumed to have occurred in the three mortalities, there was no clinical evidence of subsequent embolic phenomena in any of the other patients during their hospital stay

Comment

Hellerstein and Martin reported an 11 5 per cent incidence of clinically detectable thromboembolic lesions in 1,605 cases of myocardial infarcts [2] In their autopsy series of 160 cases of myocardial infarcts encountered in a series of 2,000 consecutive autopsies, 45 per cent had a total of 111 peripheral emboli or infarcts Sixty-five of their autopsied cases (41 per cent) showed intracardiac mural thrombi, and of these, 36 cases (55 per cent) showed evidence of peripheral occlusion of vessels as a result of either thrombus or embolus formation Of the 95 cases without intracardiac thrombi, 37 cases (39 per cent) had distal occlusion of peripheral vessels indicating the formation of thromboembolic processes in organs distal to the heart in cases where the heart did not appear to serve as the source of emboli The lungs were found to be most frequently involved, followed by the kidneys, spleen, brain, extremities, mesentery, and aorta These findings were similar to those of Blumer in his analysis of 164 autopsied cases [3] However, in 81 clinical cases, Blumer found that, following the lungs, the central nervous system was the next most common site for thromboembolic lesions followed by the vessels of the extremities, of the kidneys and surface vessels, and vessels of the spleen and aorta Pulmonary and cerebral emboli would obviously be clinically recognized because of the detectable signs and symptoms This would also hold true for the occlusion of the vessels of the extremities

On the other hand, since many of the patients who have experienced an acute myocardial infarction are so seriously ill, the small emboli to the spleen and kidney could more easily be overlooked

That arterial embolism was the most common cause of death in individuals under the age of fifty with myocardial infarction was shown by Master and his coworkers [4] In 100 consecutive cases of acute myocardial infarction at the Mayo Clinic, Nay and Barnes found thromboembolic complications in 37 of the 100 cases, and of these, the deaths of 12 could be attributed to these complications [5]

From July 1, 1946, to June 30, 1947, at the Bronx Hospital, the mortality rate among a control group of patients who experienced their initial attack of acute coronary occlusion and who received no anticoagulant therapy was approximately 20 per cent On the other hand, the over-all mortality rate in the series just presented was 9 4 per cent, with only three fatalities in a group of 32 cases Unfortunately, since per-

mission for postmortem examination could not be obtained, the exact cause of death could not be determined The striking feature of the study was the fact that there was no clinical evidence of embolism as a sequela of the acute infarction in any of the surviving cases receiving Dicumarol, as contrasted with the previously mentioned incidence among those not receiving the anticoagulant We feel, in view of this evidence, that Dicumarol therapy is indicated in acute coronary occlusion with myocardial infarction

In addition to Dicumarol, all accepted measures for the treatment of coronary thrombosis were included in the therapy Digitalis was given to those patients who developed congestive heart failure as a result of the coronary episode In spite of reports which have appeared suggesting the increase of embolism when digitalis was administered, it was felt that with the use of the anticoagulant the possibility of digitalis enhancing embolus formation was greatly lessened, if not completely overcome [5 6]

During the course of the study, heparin was given to several patients in conjunction with Dicumarol until the latter drug exerted its effect, and then the heparin was discontinued This took, usually, about forty-eight to seventy-two hours It was noted that, if blood for the prothrombin level was drawn too soon after heparin had been given, an inaccurate prothrombin reading was obtained Therefore, it was concluded, as had Wright and his coworkers and Long, Hurn, and Barker previously, that to counteract the heparin effect upon the prothrombin level, blood for the prothrombin level should be drawn just before the next dose of heparin is to be given [7 8]

Summary and Conclusions

1 Thirty-two cases of acute coronary occlusion with myocardial infarction treated with Dicumarol are presented

2 The usual therapeutic methods were employed in addition to the anticoagulant

3 The mortality rate was 9 4 per cent (three cases)

4 There was no clinical evidence of complicating embolism in any of the 29 surviving cases

5 Except for two mild cases of hematuria, there were no toxic effects of Dicumarol Use of vitamin K promptly caused subsidence of hematuria

6 Dicumarol should be used routinely as an adjunct to therapy in acute coronary occlusion with myocardial infarction

'DOCTOR JONES" SAYS—

"The Accident-Prone Individual"—that was the title of an editorial in the *J P H A Journal* awhile back. A lot of people (you've maybe known some of 'em)—they're always having accidents machinery, automobiles, falls, and what not Some of 'em, the reasons are apparent dull wits, clumsiness, carelessness, and so on The editorial wasn't referring to them These accident-prones are likely to be intelligent, thoughtful, ablebodied people

It's automobile accidents, of course, that attract most attention, especially when people other than drivers are injured. In one six-year study of traffic accidents they found that less than four per cent of the drivers were involved in 36 per cent of the accidents They're likely to lay their accidents to the "bad breaks" they've gotten Well, there's plenty of bad breaks but they're results, not causes The causes are psychologic Consciously they're anxious to avoid accidents, unconsciously, on occasion, they want to have 'em

It comes back, mostly, to this old business of unconscious reactions to childhood impressions In some cases, for example, there's hangover of childish resentment of what seemed like too much parental regulation and control—rebellion against authority Along with that there may be a feeling of guilt over the rebellion An accident, in the unconscious mind of the driver, is a double-barreled opportunity to get even with "the boss" and punish himself for his rebellion Conscious says "Sharp curve! Slow down!" Unconscious says "Step on it!" Unconscious wins and they go over the bank. There's more to it, but that's at least a peep into the works

The immediate problem, from the standpoint of public health and safety, is to spot the accident-prones and keep 'em in jobs and places where their accidents will be least likely to be serious Understanding one's accident-proneness should help to overcome it But they have to be discovered first — *Paul B Brooks, M D , September 19, 1949*

A REPORT ON THE USE OF SODIUM PTEROYL TRIGLUTAMATE IN 413 CASES

STANTON M HARDY, M D , AUSTIN L JOYNER, M D , Pearl River, New York, and RUTLEDGE W HOWARD, M D , New York City

THE purpose of this report is to indicate the nature of the results obtained during the course of clinical investigations with sodium pteroyl triglutamate on patients with late, hopeless malignancies Many physicians participated in the study, and the results observed, therefore, cannot be regarded as the work of one group but rather as the observations determined by physicians in various types of medical practice and under varying conditions The cases were not selected but represent random cases having incurable malignant tumors treated to determine the degree of symptomatic benefit which might be obtained under the conditions of medical practice

All of the patients were considered not likely to be benefited by present known methods, including surgery, radiation, and hormonal therapy These other means of treatment were used in most of the cases in this series In addition, no attempt was made by the physicians treating and observing the patients to conduct a controlled experimental study It is obvious, therefore, that some of the effects reported might have resulted either from therapy with sodium pteroyl triglutamate or from the incidental psychotherapy involved in giving any form of special treatment to a patient being treated for symptomatic results only It is to be further noted that the cases here reported were studied not for any objective effect which the drug might exert upon the tumor or its metastases but rather for the symptomatic relief which the drug might provide

Early results reported by Lewisohn *et al*, Farber *et al*, Lehv *et al*, and Leuchtenberger *et al* indicate that patients with malignant disease who exhibit pain, loss of sense of well-being, or loss of appetite may obtain symptomatic relief from the use of sodium pteroyl triglutamate [1-4] The drug was used in this series of cases, therefore, to see whether, in the hands of the practicing physician, it might prove to be clinically useful

The accompanying table shows the different types of malignant disease included in the study, together with pertinent data regarding them (Table 1)

Discussion

Analysis of the results, of course, is dependent upon the observations of the physicians who attended the patients and who were in the best position to determine whether symptomatic relief was or was not obtained Since other forms of therapy were used, including surgery, radiation, hormones, and analgesics, it might be considered difficult to evaluate the effectiveness of sodium pteroyl triglutamate with any degree of accuracy Since these other measures used in therapy of the patient did not, after a reasonable length of time—and in the case of radiation therapy after several months time—result in symptomatic relief of the patient, it is possible that, where beneficial results were observed, they can be attributed to sodium pteroyl triglutamate It is possible, of course, to reason that psychotherapy and skill in the art of caring for the patient may have been wholly responsible for the symptomatic benefit observed Additional work done elsewhere, however, in which controlled studies were made, indicates that it is the result of therapy with the drug rather than psycho-

TABLE 1.—TYPES OF MALIGNANT DISEASE INCLUDED IN THE STUDY

Disease	Total Cases	Pain Not Relieved Number	Pain Not Relieved Per Cent	Pain Relieved Number	Pain Relieved Per Cent

therapy which gave rise to the results in these patients, as well as in the controlled series [5]

Slaughter in a recent report has demonstrated, in a series of objective experiments on normal humans, that the administration of sodium pteroyl triglutamate consistently produced analgesia as interpreted by a rise in the pain threshold [6]

The fact that a significant number of patients in this series did experience some measure of relief from their symptom of pain, as well as increased sense of well-being and increase of appetite, is noteworthy It is important to note that in none of the cases reported were there any serious side actions or toxic effects The only side actions which did occur consisted of a burning or stinging sensation of short duration in those patients who received the dose intramuscularly instead of intravenously

Medication was given in doses consisting usually of 10 mg daily for the first week and 20 mg daily for subsequent weeks Most of the physicians indicated that when relief did occur it appeared within the first four weeks of therapy Thus, it would seem advisable to discontinue therapy if symptomatic relief does not occur after one month of treatment with sodium pteroyl triglutamate When pain was relieved, therapy was continued in some instances for more than one year

The nature of the relief obtained in this series may be contrasted with the relief obtained with morphine medication In the patients treated with sodium pteroyl triglutamate, when there was relief of pain there was also a psychic improvement, described by some of the reporting physicians as being a return to a normal mental outlook The mental depression and sedation, which are known to occur when morphine therapy is used to relieve pain, were not present Further, it should be noted that, when sodium pteroyl triglutamate was withheld, there was no evidence of addiction

The nature of this study does not permit a discussion as to the mechanism of the action of this new drug Further studies of a pharmacologic and physiologic nature must be awaited before the mechanism of action will be better understood

Summary

1 A report of 413 unselected cases treated with sodium pteroyl triglutamate is made to show the possible symptomatic relief to be derived from this new drug in the treatment of malignant disease

2 Statistics regarding rate of relief are given

3 A significant degree of relief indicates that sodium pteroyl triglutamate therapy will play a useful role in the care of the patient suffering from malignancy, although it cannot be expected to eradicate the malignant disease

4 It would seem advisable to discontinue therapy if symptomatic relief does not occur after one month of treatment with sodium pteroyl triglutamate

5 Further studies to determine the mechanism of action are recommended

Case Reports

PREGNANCY COMPLICATED BY ACUTE DIABETIC CRISIS

ELLIS M MARKELL, M D , Harrison, New York

(From the United Hospital, Port Chester)

DIABETES mellitus with a blood sugar of 1,000 mg per cent or more is unusual The following case is reported because of the acute onset of the diabetic state itself and the extremely high blood sugar

Case Report

M D , a nineteen-year-old, white nullipara, was first seen November 5, 1946, because of dysmenorrhea since age thirteen, primary, lasting seven to eight days, with an interval of two to four weeks Bleeding had been profuse prior to her marriage five months ago, but this had now improved No precautions had been taken to avoid pregnancy The last period had been normal in amount, painful, and had started October 20, 1946

The patient had had rheumatic fever at age thirteen with no cardiac involvement Maternal grandmother and one paternal aunt were known diabetics.

Examination revealed no abnormalities except obesity, patient being 5 feet 6½ inches tall and weighing 175 pounds Routine urinalysis was negative

It was felt that this was a case of primary pituitary-ovarian dysfunction, and, in keeping with the policy of trying the simplest thing first, she was given diethylstilbestrol, 0 1 mg once daily except during periods. For her obesity a 1,500-calorie diet was advised, and she was given a capsule, containing ¼ grain phenobarbital, ¼ grain thyroid, and ½ grain benzedrine sulfate, twice a day

The patient was next seen on December 3, 1946 at which time she was pregnant Her last menstrual period was October 20, 1946 She weighed 175¾ pounds, and she was cautioned not to gain more than 2 pounds a month Urine was negative

The patient was seen in January, February, and March and was doing well except for continued weight gain Blood pressure remained in the neighborhood of 120/80 until March 24 when it rose to 138/84 On April 28, it was 144/86, having dropped back to 128/80 earlier in April Her weight was now 203 pounds, and she was told that unless she lost weight by reducing her food intake a complication of pregnancy must be expected She was placed on a more stringent diet, with two days a week of milk and one serving of a single vegetable.

The patient was now seen weekly, and blood pressure and weight came down slightly and slowly Urinalysis was performed at each visit and was negative for sugar, with only an occasional faint trace of albumin On May 19, she complained of drowsiness, bad taste in her mouth, blurred vision, and thirst, although she was unable to drink water unless flavored with lemon and sugar She was seen at home, and no urine specimen was obtained. Blood pressure was 144/92, and toxemia of pregnancy was suspected. The next day symptoms were worse There was now thickened speech and hallucinations which progressed to disorientation She was admitted to the hospital, and her family was questioned They revealed that the patient had been showing a hunger for sweets for several weeks but within the past week had gone on a carbohydrate spree, ingesting unbelievable amounts of cola and sweet soda drinks She had had several cases of sodas in the past week and had devoured large quantities of ice cream in an attempt to assuage her thirst Mental confusion had come on gradually so that her history and complaints were completely unreliable

On admission to the Hospital on May 23, 1947, the patient was completely disoriented, had had no food for two days, but had no past history of either renal disease or diabetes Examination revealed a blood pressure of 97/50, pulse 140 and regular There was no abnormal odor to the breath. The eyeballs were soft General physical examination was otherwise negative except for a seven-months pregnancy No fetal heart could be detected at any time during hospitalization and had last been heard early the day before admission

Urinalysis showed sugar 4 plus, no acetone, no diacetic acid, albumin faint trace Blood sugar was 1,363 mg per cent at 3 P M Nonprotein nitrogen was 60 mg per cent

Thereafter, urine was obtained hourly from an indwelling catheter, with regular insulin, 20 units for 4 plus sugar down to 10 units for 1 plus Another blood sugar determination at 8 P M showed 1,100 mg per cent

Blood sugar determinations were as follows

May 23—	3 P M	—1,363 mg per cent
	7 P M.	—1,100
May 24—	3 A M	— 500
	9 A M	— 207
	11 P M.	— 450
May 26—	9 A.M.	— 375
May 28—	9 A.M.	— 333
May 31—	9 A.M	— 187

When the sugar level fell to 207 mg., insulin was stopped, and the patient was allowed a meal of orange juice, toast, and milk. On May 26 her mental confusion was almost over in spite of the rise in blood sugar She was allowed a diet of 100 Gm. carbohydrate, 50 Gm protein, and 50 Gm. fat, and insulin was ordered on a sliding scale of 35 units for 4 plus glycosuria down to 10 units for 1 plus On May 27 she was given bathroom privileges, and the diet was increased to 120 Gm. of carbohydrate, with 60 Gm. each of fat and protein. On May 28, she received 20 units of globin insulin with her regular insulin on the same sliding scale On May 30

globin insulin was increased to 30 units, and the regular insulin cut to 25 units for 4 plus On June 1, she was given 40 units of globin insulin, and the regular insulin was limited to 15 units at 7 30 P M

The urine during this entire period showed acetone only in occasional traces Sugar fell from a steady 4 plus to negative, and the patient was discharged from the hospital on June 1 on globin insulin, 40 units daily, and a diet of 120 Gm. carbohydrate, 60 Gm. protein, and 60 Gm fat At home, she tested her urine each morning and afternoon After two days insulin was dropped to 25 units Next day, all urines being negative, she took only 10 units, and this was her last dose of insulin

Although no fetal heart was detected from the time the patient became disoriented, labor did not ensue Finally, on June 20, she was readmitted to the hospital Her blood pressure was 98/50, urine was negative, and general health appeared good There had been no growth of the uterus, and it appeared definite that the fetus was dead Induction of labor with castor oil and seven doses of 1 cc each of nasal pituitrin was unsuccessful, so she was taken to the delivery room, and under aseptic condition the membranes were ruptured with difficulty About 100 cc of dark, brownish amniotic fluid was drained Three million units of penicillin in wax and oil were given before instrumentation and daily for five days thereafter Active labor started five and one-half hours after rupture of membranes, five hours and twenty minutes later she was delivered spontaneously of a 3-pound, 13-ounce stillborn which showed very little maceration The placenta appeared normal, showing no significant degree of infarction

Laboratory work-up during this hospitalization showed a blood sugar of 88 mg per cent, negative urine, normal complete blood count, and Rh positive blood Postpartum course was completely uneventful The patient had gradually gone on to a normal diet at home so the only regulation given in the hospital this time was elimination of some of the sweeter foods at the patient's own discretion. There was no return of glycosuria during hospitalization nor at any time since Urine is tested at weekly intervals

Comment

This case presented several interesting points. The blood sugar was the highest ever recorded at the United Hospital in Port Chester, New York. There was never any clinical evidence of diabetes, and the urine was sugar free until the weight climbed to over 200 pounds Fetal heart was heard after the onset of symptoms so diabetes cannot be considered to have been precipitated by failure of the fetal pancreas The most interesting clinical observation was the fact that this severe diabetic state came on as rapidly as it did, in a patient who was under continuous observation, including frequent urinalyses and, when the sugar did appear in the urine, the highest acetone was one plus with no diacetic acid Another point is the fact that, following termination of the acute episode, the whole picture cleared to the extent of the patient having no further evidence of diabetes mellitus I look upon this as a case of acute pancreatic failure due to severe pituitary dysfunction

The patient was seen in consultation by Dr Morton Ryder, who has reviewed this report Dr Ryder spent considerable time both with the patient and in the laboratory, and it was his patience and guidance which resulted in her apparent cure

Summary

A case of severe, perhaps total pancreatic failure during pregnancy in a patient with no previous or subsequent diabetic history is presented, with apparent cure following fetal death

275 Harrison Avenue

NEW TYPE OF INSULIN AIDS DIABETICS

A long-acting insulin which reduces the number of injections needed by diabetics has been developed, according to an article in the October 1 issue of the *Journal of the American Medical Association*

Duration of blood sugar lowering action of the new modified protamine insulin (NPH-50) is 28 to 30 hours, while that of other kinds of insulin is six, eight, 15, and 72 hours according to Dr Priscilla White of Boston, Massachusetts

In 95 per cent of the 336 persons with severe diabetes to whom the new insulin was administered, results were as successful as, if not more so, than those from separate injections of crystalline and protamine zinc insulin

In 5 per cent of the group, a single injection of the new insulin was less successful in controlling diabetes than were separate injections of these two insulins These failures included insulin-sensitive adults, diabetic children under five years of age, and patients whose requirements for long-acting insulin were small compared with their requirements for quick-acting insulin

Regulation of diet and exercise is a necessary adjunct to treatment with the new insulin

AUREOMYCIN IN THE TREATMENT OF VIRUS PNEUMONIA

RICHARD B CUTHBERT, JR , M D , Canastota, New York

(From the Lenox Memorial Hospital)

WHILE it is becoming generally agreed that aureomycin is of marked value in the treatment of primary atypical and virus pneumonias most of the cases reported to date have been in adults. Schoenbach and Bryer in their series of 13 cases present two in children of ten years of age, and Kneeland *et al* in their series of ten cases include one of a child of eleven [1,2] In view of this scarcity of reports on children, it is felt that the following case may add to the total experience and be of service in evaluating the management of younger patients with this antibiotic The diagnosis in this case depends largely on the criteria outlined by Kneeland *et al* and by Appelbaum [2,3]

Case Report

S C , a girl, age eight, weighing 65 pounds, complained of an ache in her neck on January 27, 1949 It was found that she had a temperature of 100 F but otherwise there were no physical signs She continued to run a septic type of temperature but did not develop any physical signs until January 29 when she began to exhibit a dry, hacking cough A chest x-ray taken on this date showed a small area of patchy infiltration in the lower lobe of the right lung The patient was started on penicillin therapy This antibiotic was discontinued two days later (January 31) after administration of 600,000 units It was discontinued because the temperature had continued to spike, having reached a peak of 103 6 F , and because repeat x-ray of the chest on this date showed an extension of and an increase in the opacity of the involved area. There were no symptoms other than the nonproductive cough and the fever and no physical signs other than a slight diminution in resonance over the right base posteriorly The child was treated symptomatically until February 3, on which date x-ray of the chest showed consolidation involving almost the complete lower lobe of the right lung, with general increase in the root markings of both lungs (Fig 1) It was felt that the child was suffering from a virus type of pneumonia, and this diagnosis was supported by a positive cold agglutinin test in titer of 1 64

Aureomycin therapy was started on a dosage of 0 5 Gm. every six hours, which is approximately 66 mg per Kg of body weight per day Temperature reached normal sixteen hours after the institution of the therapy and remained there or below for the rest of the course of the illness X-ray taken forty-eight hours after the start of the therapy showed almost complete disappearance of the consolidation (Fig 2), and a plate taken ninety-six hours after the first dose of the aureomycin showed only patchy infiltration in the area that had been consolidated when the first dose was given

The aureomycin was continued on the original dosage schedule (0 5 Gm every six hours) until the child had received a total of 12 Gm. of the antibiotic Her temperature remained normal At no time were physical signs elicited other than the septic temperature and the relative dullness at the right base posteriorly No symptoms were noted other than the usual reactions to temperature changes and the hacking cough This became somewhat looser on the fourth day after aureomycin but continued to be unproductive The child was allowed out of bed on the seventh day after aureomycin was started, and she returned to school on the

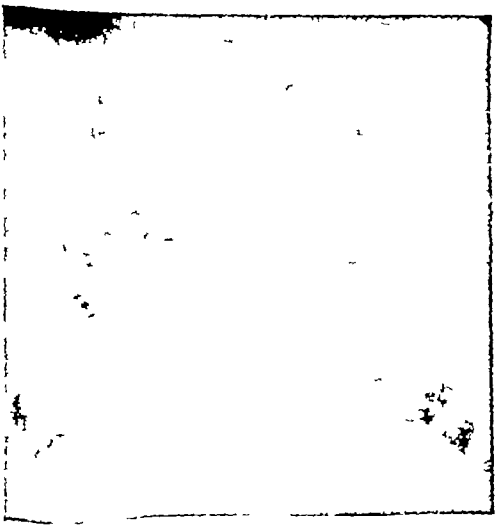

FIG 1 X-ray taken on February 3, 1949, prior to administration of aureomycin

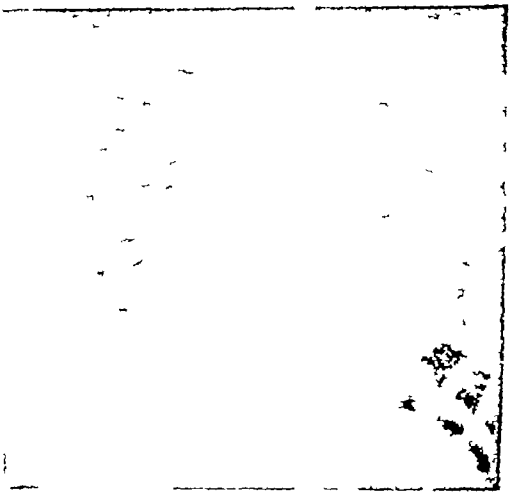

FIG 2 X-ray taken on February 5, 1949, after administration of 4 0 Gm aureomycin

eleventh day after its institution, the eighteenth day of the illness

Laboratory examination on February 1, 1949, was as follows Urine entirely normal, erythrocyte sedimentation rate (Wintrobe) 11 mm per hour, white blood cells 7,000, polymorphonuclears 54 per cent, nonfilamented forms 13, and lymphocytes 41 On February 3, the cold agglutinin test was positive in a dilution of 1 64 *On February 4, the white* blood cells numbered 8,500, polymorphonuclears 56 per cent (nonfilamented 21), and lymphocytes 34 per cent On February 9, there were 4,600,000 red blood cells, 13 8 Gm hemoglobin, 9,000 white blood cells (15 nonfilamented), and 40 per cent lymphocytes On February 15, the cold agglutination test was positive in a dilution of 1 256

Observations on the reaction to aureomycin were as follows After the child had received 1½ Gm of the aureomycin, she complained of nausea which lasted for two hours She did not vomit About an hour after taking the dose that brought the total dose to 4½ Gm , the patient suddenly vomited without having been previously nauseated A yellowish color was noted in the vomitus, and it is felt that she lost some of the medication at this time There were no subsequent attacks of nausea or vomiting It was noted that in each of the above episodes, the medication had been given when the patient's stomach was empty At other times she did not seem to be upset by the medication After the total dose of aureomycin had reached 5 Gm , the patient's stools became softer than normal, but there was no true diarrhea There were no other signs or symptoms that could have been construed as toxic reactions to the medication, and it will be noted that no anemia resulted from its use

Summary

1 A case of virus pneumonia in a child of eight years is reported Aureomycin therapy was employed with rapid and very satisfactory results

2 Aureomycin was given in doses of 0 5 Gm. every six hours The dosage was not reduced as the illness progressed, and the total dose of the medication was 12 Gm The medication was well tolerated in relatively large doses, and no significant toxicity was noted

USE RADIOACTIVE COMPOUND TO CONTROL RARE BLOOD DISEASE

Control of the rare and previously fatal blood disease, polycythemia vera, a condition in which the body manufactures red blood cells too rapidly, was reported by Dr John H Lawrence of the University of California, Berkeley, in the September 3 issue of the *Journal of the A M A*

In the treatment developed by Dr Lawrence and his colleagues, a compound (sodium radiophosphate) containing radioactive phosphorus is administered This chemical collects "to a pronounced degree" in bone, bone marrow, and some rapidly growing tissue and apparently inhibits red cell production

Persons treated for polycythemia vera with the radioactive compound now have as favorable an outlook as do those treated for sugar diabetes with insulin or those treated for pernicious anemia with liver, Dr Lawrence says He bases his conclusion on a ten-year study of the treatment of 172 patients

Average age at the onset of the blood disease in the series of patients was 50 7 years, and the average age of those patients who died was 67 years. This is nearly a normal life expectancy for persons in this age group, Dr Lawrence points out

---

OPERATION FOR GANGRENE REVERSES BLOOD STREAM

A new operation that "runs the blood stream in reverse" was announced recently by Wayne University physicians seeking a better treatment for gangrene of the leg

Working on the treatment are Drs Charles Johnston, E S Gurdjian, Prescott Jordan, John E Webster, and Gordon H Scott, *acting dean of the* Wayne Medical School

The operations, the first of which was performed last winter, are carried out by Drs Johnston and Jordan in Receiving Hospital Dr Jordan said the operation had been performed fourteen times with "encouraging" results

The operation consists of channeling blood from an artery in the thigh into a vein Normally, blood in the vein flows toward the heart, but after it is tied to the artery, the blood flows away from the heart to the affected limb *The reversal is possible because* arterial blood flows faster than venous blood can displace it —*New York Times, September 3, 1949*

PRIMARY TUBERCULOSIS OF THE PAROTID GLAND TREATED WITH STREPTOMYCIN

JOSEPH H HERSH, M D , New York City

TUBERCULOSIS of the parotid gland is not common. Cases of both primary and secondary involvement have been reported in the literature during the last fifty years In 1932, Berman and Fine reviewed the literature to date and reported an additional case [1] Since then nine additional articles have appeared, each reporting from one to six new cases.[2-10] Treatment has varied, and good results have been reported with surgical extirpation, as in Berman and Fine's case No case report could be found in which streptomycin or other antibiotic agent had been employed

Case Report

S R , a nineteen-year-old white boy, complained of a swelling on the left side of his jaw It had been noticed about six weeks previously and had gradually increased in size It was not tender or inflamed

The patient's past history contributed nothing pertinent to the present complaint He did state that his father had pulmonary tuberculosis, that he was under treatment by pneumothorax for two years, and that he lived at home

Examination revealed a ruddy-faced, obese young man On the left side of his face, just below the lobe of the ear and covering the angle of the jaw, was a subcutaneous mass that was doughy in character, unattached to the skin, and sharply demarcated posteriorly but blending with the parotid gland anteriorly It measured 1 inch in diameter and protruded 1/4 of an inch above the surrounding skin surface. A 16-gauge aspirating needle was plunged into the mass, but nothing could be pulled back into the syringe

The general physical examination, chest roentgenogram, complete blood study, serologic examination, and urinalysis disclosed no abnormalities

The presumptive differential diagnosis was as follows (1) mixed cell tumor of the parotid gland (2) chronic, infectious granuloma of the parotid (tuberculosis, Hodgkin's disease, etc), (3) parotid gland malignancy

On April 10, 1947, under local anesthesia (procaine 1 per cent) a curved incision was made, starting in the preauricular crease and extending downward and forward under the angle of the mandible The skin was freed and reflected in two flaps posteriorly and anteriorly to uncover the tumor mass This was picked up posteriorly where it was clearly defined and well encapsulated By blunt dissection it was freed anteriorly until it was found to merge with and become indistinguishable from the parotid gland The tumor mass was pale gray, friable, and had scattered yellow nodules Because a total gland excision had not been contemplated, the freed mass of tumor tissue was cut away, and the wound was closed with interrupted black silk sutures

Wound healing was uneventful The parotid enlargement was persistent

Microscopic examination revealed the tissue to be made up of hyperplastic epithelioid tissue which replaced the usual parotid structure that was represented merely by occasional clumps of tubules (Fig 1) There were scattered tubercles with occasional giant cells and caseating centers Large areas of caseation were also seen Diagnosis was tuberculosis of the parotid gland

FIG 1 A high power photomicrograph displaying a residuum of parotid tubules, the epithelioid hyperplasia, and the adjoining necrosis

Streptomycin therapy was instituted, 1 Gm per day being administered for a period of six weeks The parotid mass gradually receded At the end of the sixth week it was no longer evident The patient has been examined at frequent intervals for a period of two years, and there has been no sign of recurrence

ROLE OF COUNTY SOCIETY MEMBERS IN MEDICAL LEGISLATION

FREDERIC W HOLCOMB, M D , F A C P , Kingston, New York
(*Vice-Speaker, Medical Society of the State of New York*)

EVERY physician who is engaged in the practice of medicine in our State should realize that there has been a tremendous increase during the past few years in both the problems and the volume of legislation relating to public health, workmen's compensation, hospital administration, care of the indigent and aged, and many other fields of concern to the members of our profession These problems are of concern to us, not only from a medical, but from an economic standpoint as well The trend toward political or bureaucratic medicine is developing rapidly, and we must strive to the best of our ability to guide and modify this trend so its development will be in the best interests of sound medical practice The results of our legislative efforts for the State Medical Society during the past year were rather disappointing in several respects This leads us to attempt an analysis of our program and to try to correct the weaknesses in our organization

In our State Society we have an approximate membership of 22,000 physicians, as compared with a voting population of about six million in New York State It can easily be seen, therefore, that if our Society membership represents only that relatively small number of votes, the disproportion must be compensated for by each member extending his or her influence to a large number of the voting population We must realize that legislators are elected, re-elected, or defeated by votes, and votes alone They are in office as possessors of political acumen, and their actions and opinions are guided by votes and potential votes, and not, as are ours, by love or devotion to the science of medicine We must also realize that many groups much larger than ours, such as labor unions and large corporations, employ representatives or so-called lobbyists in Albany These representatives attempt to influence legislation in which their groups are interested, and most of them are supplied with ample funds for expense accounts and entertainment to assist them in presenting their viewpoints to Senators and Assemblymen It is apparent, therefore, that in order to carry on a worth-while program, with the twofold purposes of informing the legislators of our opinions on medical legislation and keeping our membership alerted on matters pertaining to them, we must increase both our personnel and our budget

We must also recognize the fact that the legislators in the State capitol are in many instances under the influence of several groups having not only varied interests, but often very conflicting ones An able and conscientious legislator is often confronted with different, even opposite opinions regarding certain measures and is subjected to pressure by various labor, business, and professional organizations This makes it necessary for him to weigh carefully the various possibilities before choosing his stand on a given question, in the hope of making laws which are fair and beneficial to the greatest number of people

What can be done about the apathy and indifference on the part of our physicians concerning medical legislation? I feel that the present set-up in the State Society's organization is basically adequate but must be expanded to meet the ever-increasing needs Our weakness lies in the indifference and complacency of the average practitioner, who seems to expect a very small group of men to carry on the work in this field for 22,000 members. This group on whom the burden now falls includes our only legislative officer in Albany, Dr Robert R. Hannon, the State Legislative Committee, and the chairmen on legislation from the respective county societies It is only by kindling the interest and efforts of each and every practicing physician that we will be able to influence the votes of our Senators and Assemblymen

Every legislator with whom I have discussed this matter admits readily that the medical practitioner possesses tremendous potential political influence. As a rule, the doctor occupies a position in the community that commands respect for his opinions—particularly on matters regarding public health and medical care, but—and the legislators seem equally unanimous in this observation—the doctors are apparently too indifferent or too lazy to exercise even a small fraction of their influence Until this situation is altered, I repeat that it is both futile and unfair to expect a small group of men to carry on the work of 22,000 Before any of us complain to our county societies about adverse legislation being passed, or medically beneficial laws being defeated, let us question ourselves along these lines How much time and effort have *I*, as an individual, expended in the past few years, toward influencing the passage or defeat of medical legislation in New York State? Your State Society will have the organization capable of informing you as members on matters pertaining to medical and public health legislation, but, without your *active* participation in the program, it can do no more in the future than it has in the past The proper expansion of our program in Albany depends largely upon your efforts to influence the passage of beneficial legislation

To summarize, I offer the following suggestions

1 Each physician in the State Society must realize that the medical legislation affects him, both professionally and economically

2 Let each physician counsel his patients and associates wisely and unselfishly concerning matters of important medical legislation

3 A special meeting should be called in each county society following the State Society's Legislative Conference in Albany At this time the respective county societies should discuss and pass resolutions on the most important bills

4 Each Senator and Assemblyman in the district should be promptly informed as to the Society's opinions and actions on such bills

5 The Legislative Committee of the State Society should send promptly to every physician pamphlets giving a short analysis of the most important bills These pamphlets, for distribution to the lay public, may well influence patients and friends to inform their representatives in Albany as to their opinions on medical legislation

Presented at the Forty third Annual Meeting of the Fourth District Branch Medical Society of the State of New York Friday September 16 1949 Saranac Lake New York

SUMMARY OF MINUTES OF THE COUNCIL OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

AT ITS meeting on September 8, 1949, the Council considered the following matters, taking action as indicated

Secretary's Report

Remission of Assessments—Remission of annual assessments was voted on account of service with the armed forces for two members for 1949 and two for 1948, and, on account of illness, eleven for 1949 and one for 1948 Eight War Memorial assessments were remitted because of illness or service with the armed forces

Communications—1 Letter from Mrs Leon Gross, Fort Worth, Texas, as follows

Dear Sirs

Enclosed please find my check for one hundred dollars ($100), given as a memorial to Dr Albert D Mayer of the Hotel Surrey, your city, who passed away July 28, 1949

Also a check ($100) as a memorial to Dr A D Mayer from R J Mayer

It was voted that the disposition of these funds be left to the discretion of the Board of Trustees

(The Board of Trustees voted to assign these generous gifts to the War Memorial Fund)

2 Memo from Dr George F Lull, secretary and general manager, American Medical Association

As of July 28, 1949, our records show that your association had remitted 41 per cent of the twenty-five dollar assessment Its relative standing in per cent collected among the 53 constituent societies was 47

It was voted that the matter be referred to the Public Relations Committee to devise means of collecting the outstanding assessments

3 Letter from Mr William C Stronach, executive secretary, The American College of Radiology, dated August 1, 1949

The American College of Radiology views with alarm and dismay all proposed programs relating to the distribution of medical services which place the diagnostic aspects of medicine in a category apart from the general practice of medicine

The Chair referred the letter to the Managing Editor of the NEW YORK STATE JOURNAL OF MEDICINE for publication

4 Letter from Mr H H Barton, president of the Chamber of Commerce of North Creek, New York, July 20, 1949, expressed thanks that Dr Jacques Grunblatt is beginning practice at North Creek "Yours was a valuable service to our community and we thank you sincerely"

It was voted to refer this to the Public Relations Committee and to the Managing Editor of the NEW YORK STATE JOURNAL OF MEDICINE

5 As a result of a letter from a member protesting refusal to renew his participation in group malpractice defense insurance,

It was voted that he and the chairman of the Malpractice Insurance and Defense Board be invited to appear at the next meeting of the Council.

6 Two letters from the U S Pharmacopoeial Convention, thanking the Society for contribution of $100 to their building fund, were received

7 Letter from Dr Ernest B Howard, June 29, 1949, including resolution from the American Medical Association and letter from Dr L Fernald Foster, secretary, Michigan State Medical Society, in regard to H R Bill 2893

The Secretary reported that appropriate action had been taken during the summer

8 Letter dated July 5, 1949, from Commissioner Robert T Lansdale, New York State Department of Social Welfare, expressing appreciation of work done by Dr Christopher Wood former chairman of the Committee on Public Medical Care

9 Letter June 28, 1949, from Dr Albert Vander Veer, 2nd, secretary of Medical Society of the County of Albany, recommending changes in the Workmen's Compensation Fee Schedule, was referred to the Workmen's Compensation Committee

10 Letter July 29, 1949, from Dr Joseph A Lane, secretary, Medical Society of the County of Monroe, re so-called Linowitz Plan

By action of the Comitia Minora on July 11 this letter is addressed to all secretaries of county medical societies in New York State, calling to your attention the Linowitz Plan, which seeks to induce voluntary health insurance

The Comitia Minora, feeling that this is a positive step to make voluntary insurance possible to a greater number, endorsed it unanimously A copy of the plan is included herein, and we hope that your society after due consideration will concur with the Monroe County Medical Society in taking similar action

It is our hope that the Medical Society of the State of New York will join with other state medical societies in endorsing this proposed plan

It was voted to refer this to the Committee on Economics

11 Letter from Dr Robert H Hannon, Executive Officer, requesting additional appropriation of $152 58 for meetings of executive committees of district branches (The original appropriation was $500 but unexpected attendance and increased costs had raised the expenses)

It was voted that the Board of Trustees be requested to appropriate $152 58 to eliminate the deficit

(The Board of Trustees, after due consideration, voted to meet this unexpected expense)

12 The request of the Medical Society of the County of Steuben for remission of Dr George Allen Sisson's assessment for 1949, because of his residency for three years, was denied (The Council does not have power to remit assessments for any cause except illness or service with the armed forces)

13 Letter August 22, 1949 to Dr James R Reuling from the Oklahoma Division of the American Cancer Society, through the New York City Cancer Committee of the American Cancer Society, inquiring amount spent during the year by the State Society on the study and control of cancer was referred to the Committee on Public Health and Education

14 Letter July 11, 1949, from Mr Leslie P Huey of the Eisenstadt Manufacturing Company, St. Louis, regarding award to physicians who have been practicing fifty years or longer

After discussion, *it was voted* to refer this to the Public Relations Committee for study and report

15 Letter, dated September 1, 1949, from Miss Mary Donlon, chairman of the Workmen's Compensation Board

Dear Doctor Anderton

On my return from Europe I find your letter of July 14, which was acknowledged by my secretary on July 15

I am interested to learn that the House of Delegates of the Medical Society of the State of New York has recommended approval of thoracic surgery as a separate specialty

This recommendation indicates that, in the judgment of the House of Delegates, specialists in general surgery are not qualified in the operative procedures of thoracic surgery and that disabled workers in need of thoracic surgery should be entrusted only to the care of specialists in that field May I therefore request your cooperation in defining the area of the new specialty from which specialists in general surgery should be excluded

For this purpose may I suggest that the President designate three members of the Society who are especially qualified in thoracic surgery and also three members who are qualified as specialists in general surgery, but not in thoracic surgery, so that I may consult with them and have the benefit of their recommendations as to the field in which operative procedures by general surgery specialists should not be recognized under the Workmen's Compensation Law

After discussion, *it was voted* that the President be authorized to appoint such committee

16 Correspondence between Mr Robert Dwyer of *The News*, Dr Drabkin, secretary of Nassau County Medical Society, Mr Richard W Clarke, executive editor, News Syndicate Company, Inc, and Dr Anderton in regard to an article entitled "M D 's Unorthodox Ideas Give Heart Patients Hope," written by Mr Dwyer

It was voted that the President answer Mr Dwyer's letter according to the sentiments expressed by the members of the Council and also extend to him an invitation to meet with the President and the Public Relations Bureau of the State Society for a friendly discussion of the point at issue

It was voted that the entire matter be referred to the Nassau County Medical Society for discussion in open membership on the floor

17 Letter dated July 18, 1949, from Group Health Insurance, Inc , requesting consideration and approval of its medical and surgical care insurance plans by the State Medical Society

After discussion, *it was voted* that this be referred to the Committee on Economics with the privilege of consulting with other committees

Your Secretary has attended all committee and board meetings

A question has arisen as to whether or not the Council desires to continue the policy of remitting the annual assessment for members who have remained in the armed services since World War II The 1941 House of Delegates voted power to the Council to make such remissions upon recommendation of a member's county society

It was voted to continue the policy of remitting the dues for members who are temporarily in the armed services

Appointments authorized by the Council and made by the President.—Dr Milton G Potter, Buffalo, to represent the Medical Society of the State of New York at meetings of the Board of Directors of the Mental Hygiene Clinic for the Study of Alcoholism University of Buffalo School of Medicine

Dr Charles Solomon, Kings, to represent the Medical Society of the State of New York at the 1950 meeting of the Committee of the U S Pharmacopoeia

Dr Carlton E Wertz, President-Elect, delegate to the annual meeting of the Vermont State Medical Society

Dr Masterson, with the approval of the Council, appointed Dr James R. Reuling and Dr J Stanley Kenney representatives to the annual meeting of the Medical Society of the State of Pennsylvania, September 26 to 29 in Pittsburgh

The Treasurer's report was accepted

Reports of Committees

Legislation.—Dr Dattelbaum, chairman, presented the following report

The Committee recommended that the Albany staff be augmented by an additional legislative expert

After discussion by the Council, *it was voted* to carry out this recommendation

It was voted that the matters of interviewing individuals for the position of legislative expert and remuneration be referred to the subcommittee of the Committee on Legislation, consisting of Drs. Masterson, Hannon, Ayers, Dattelbaum, and the legal counsel

The Legislative Committee recommended that all news releases be sent to Dr Hannon's office to be checked by him This was discussed

It was voted that this should be accomplished by the Legislative Committee working in conjunction with the Public Relations Committee

Subcommittee on Lien Law appointed as follows Drs Kottler, Hollis, and Edwards (Dr Hannon said he would like to have this subcommittee see Senator Friedman and discuss with him any recommended changes in last year's bill)

The following subcommittee was appointed to discuss with the other interested professions an injunction bill for appropriate professions, to be introduced in the 1950 Legislature, Dr Holcomb chairman, Drs Dickson and Lochner, Mr Bell, Mr Martin, or Mr Clearwater (legal counsel)

The committee recommended that Mr Martin counsel, should look into the matter of the legality hospitals practicing medicine

The Legislative Committee recommended that the Council suggest to county societies the importance of appointing to their legislative committees only members interested in the work and that they have a vice-chairman trained to take over the position of chairman, if for any reason the latter could not continue

The Committee also recommended that the county societies be notified that the special legislative meeting should be held once a year by each county society, after the annual meeting of the chairmen of county society legislative committees Each county legislative chairman should draw up an agenda and discuss the most important bills

Approval was voted

A subcommittee consisting of Dr Kottler, chairman, and Drs Needham and Lawrence was appointed to contact radiologic societies about the proposed x-ray bill and endeavor to obtain approval.

Medical Indemnity Payment Introduction of legislation to preserve free choice of physicians under

oluntary medical insurance plans —It was suggested hat this matter be considered by the Council and lso discussed by the Medical Expense Insurance ubcommittee It was also recommended that the itter Subcommittee study the Panken Bill (Senate ntro 1231 of year 1949) and that no further action n it be taken, until approved by the Council

Workmen's Compensation Legislation affecting ounties having population of over one million —The Committee recommended that the bill to abolish the Medical Practice Committee be reintroduced following a conference between the chairman of the Workmen's Compensation Board and members to be appointed by Dr Masterson from Erie and Westchester Counties, and Dr Kenney No action was aken.

Group Practice —It was reported that the Legislative Committee will inform the House of Delegates hat, after serious consideration, it was decided that his is not the proper time to introduce the type of egislation proposed, which would attempt to harmonize the Workmen's Compensation Law and the Medical Practice Law as affecting group practice

Disability Benefits Law —The Committee recommended amendments be withheld for the present until it can be seen how the law works

The President requested the Committee to bring in an additional report at a subsequent meeting

Revision of the Medical Practice Act —The Legislative Committee recommended to the Council that committee be appointed to confer with the Department of Education about amending the Medical Practice Act

Approval was voted for the chairman to appoint this committee

Legislation Regarding Alcoholism —Dr Hannon read a letter from E H L Corwin, Ph D , of the New York Academy of Medicine (June 29, 1949), and a copy of his reply (July 15, 1949) He also referred to a memo received from Dr Milton G Potter, chairman of the Committee on Problems of Alcoholism. The Legislative Committee decided that this should be left to the Committee on Problems of Alcoholism and that action should not be taken until a report is received from Dr Potter's Committee

Re Osteopaths —Dr Hannon read a memo from Dr Nat Kanner of Brooklyn, suggesting that osteopaths be required to use the title "D O ", or the word "Osteopath" on all letterheads, signs, etc

The Committee suggested to the Council that this body recommend to county medical societies that all members use "M D " on prescription blanks, letterheads, signs, etc ,—also that the JOURNAL make a note of this fact

Introduction of Legislation Concerning Anesthesiology, Psychiatry —The Committee recommended that the Council appoint a committee to work with the anesthesiologists and psychiatrists in regard to legislation to be introduced in the next session of the Legislature

The Council *voted* to refer this to the Joint Committee of the Hospital Association of New York State and the Medical Society of the State of New York, and that a representative psychiatrist be invited to participate in the proposed discussions, as well as the members of the State Society's subcommittee of the above committee

Problems of Alcoholism.—Dr Potter, chairman, sent the following report

At a Committee meeting held in Buffalo, August 4, 1949, the following action was taken and Council approval is requested

1 That the policy of the Committee be Encouragement and aid to education, rehabilitation, proper legislation, and research in the problems of alcoholism.

2 *Education Policy* (*a*) Due to the poor results obtained last year from letters sent to the county societies by the chairman of this Committee, encouraging the formation of local committees on this subject, it is recommended that an appropriate letter, composed by the chairman of this Committee, be signed by the President and sent to each county society, an answer to be requested from each county society

It was voted that this be done if the letter is approved by the President

(*b*) That the President and the President-Elect when addressing district branch meetings and local county meetings emphasize the importance of the formation of these local committees This is recommended because it is not possible at this late date for members of this committee to get on the programs

(*c*) That the President be instructed by the Council to send letters to the various deans of the medical schools in New York State requesting information concerning the nature and extent of courses given on the Problems of Alcoholism A survey such as this is needed before suggestions can be offered by the Society

It was voted that the President request the chairman of the Committee to solicit this information

3 *Rehabilitation* (*a*) That the present limited New York State Pilot Demonstration Clinic Hospital program operated by the Medical School of the University of Buffalo, sponsored by the State Mental Health Authority, suggested by the Subcommittee on the Problems of Alcoholism to the Interdepartmental State Council and financed by Federal funds allocated to New York State under the Mental Hygiene Act, be supported and be greatly expanded to include 1 Experimental convalescent care for those patients no longer requiring active hospitalization but who cannot return to their home environment until a further period of rehabilitation is allowed, 2 An experimental long-term rehabilitation program to evaluate technics, values, and possibilities for those cases which require hospitalization rather than ambulatory treatment

Approval was voted

(*b*) That the Council approve the suggestions contained in a letter to Dr Hilleboe dated July, 1949, from the chairman of this Committee

Approval was voted

(*c*) That the Council approve the suggested State program for Alcoholic Addiction proposed by the Subcommittee on the Problems of Alcoholism to the Interdepartmental Health Council of the State of New York omitting Article 3 except the last paragraph, only after the initial pilot program has been expanded, perfected, evaluated, and its worth proved in the community for the care of patients in the various stages of the disease on a practical economic level.

Approval was voted

4. That the Council strongly objects to the action of the Advisory Council to the Department of Mental Hygiene of New York State in stopping the appropriation of Federal funds for the State Pilot Demonstration before it has really gotten under way The objection should take the form of a letter or a request for a hearing with the Governor only after failure to get results by personal interviews with key members of the Advisory Council to the Department of Mental Hygiene and the Governor's personal physician, by members of the Committee

It was voted to send this back to the Committee for further study and elucidation

5 That if there is failure to obtain continued Federal funds for this demonstration, legislation should be originated by the Interdepartmental Council of the State and the New York State Medical Society for a definite appropriation to carry out this initial program, prior to initiating legislation and an appropriation for a State-wide program

It was voted that this be referred jointly to the Committee on Problems of Alcoholism and the Legislative Committee

6 That the Interdepartmental Council of the State of New York (Dr Hilleboe, chairman) be notified by the President of the action taken by the Council upon the suggestions of the Special Committee on the Problems of Alcoholism

It was voted that the President request the Secretary to write to Dr Hilleboe

Constitution and Bylaws—Dr Reuling, chairman, reported that changes submitted by the Medical Society of the County of New York in their bylaws had been studied by members of the Committee and by the attorney, and as there was nothing inconsistent between them and the State Society's Constitution and Bylaws, approval was recommended

Approval was voted

Convention—The Convention Committee reported that the 143rd Annual Convention of the Medical Society of the State of New York was held at the Hotel Statler in Buffalo from May 2 through 6, 1949

Close to 2,500 registrations were recorded It is possible that some physicians who attended the scientific meetings on the lower floors did not register on the 17th floor of the hotel

The registrants were

Physicians	1,609
Guests (medical students, interns, nurses, medical technicians, dieticians, and others)	538
Exhibitors (technical)	335
Total	2,482

The Scientific Awards Committee conferred a First Award, Second Award, and Honorable Mention in two classes Clinical Research and Scientific Research Beribboned plaques were pinned on the winning exhibits and certificates of award sent to the winners

The following were the recipients

Clinical Research First Award—"Low Toxicity of Sulfonamide Mixtures," Dr David Lehr, New York Medical College, Flower and Fifth Avenue Hospitals, New York City, Second Award—"Etiologic Diagnosis of Heart Disease," Dr Charles A. R Connor, American Heart Association, Inc, New York City, Honorable Mention—"Gold Toxicology in Rheumatoid Arthritis," Dr Charles LeRoy Steinberg, Rochester General Hospital, Rochester

Scientific Research First Award—"Radio Isotopes," Nathan H Woodruff, Ph.D, Mr G William Morgan, and Mr Carroll N Bowman, Isotopes Division, United States Atomic Energy Commission, Oak Ridge, Tennessee, Second Award—"Sponge Biopsy A New Method in Cancer Diagnosis," Dr Sidney A. Gladstone, New York Polyclinic Medical School and Hospital, New York City, Honorable Mention—"New Method for Roentgen Anatomic Study of the Skull," Dr Lewis E Etter, Western State Psychiatric Institute and Clinic Pittsburgh, Pennsylvania.

Economics—Mr George Farrell, director, Medical Care Insurance Bureau, reported he had spoken on medical care plans before several meetings

Following the request made by the House of Delegates that further consideration be given to a uniform State contract for medical care insurance, Mr Farrell conferred with Dr A. H Aaron, chairman of the Subcommittee on Medical Expense Insurance and reviewed a comparative fee schedule and questionnaire on contract provisions of each plan, requested by the Subcommittee The questionnaire and comparative fee schedule were prepared by the Bureau and sent to all plans in New York State for return by September 1 This material is to be analyzed by the Bureau for presentation to the Subcommittee

Mr Farrell presented the semiannual report on the six plans approved by the Medical Society of the State of New York

The report was *approved*

Dr Azzari, chairman, reported on matters referred to the Economics Committee by the Council at its June meeting, as follows

Practice of Medicine by Hospitals and Colleges—That all Blue Cross and Blue Shield Plans in New York State be notified that the Medical Society of the State of New York recommends that Blue Cross discontinue offering medical services in pathology, radiology, anesthesiology, and physical therapy, and that Blue Shield Plans should pay for these expenses

Medical Indemnity Payments—Recognizing that contract restrictions under certain voluntary insurance plans tend to deny or restrict the free choice of physicians, the House endorsed in principle legislation to preserve free choice of physicians especially in cases where there are indemnity payments under voluntary medical insurance plans The Committee discussed this particular mandate of the House and recommends its approval by the Council

Approval was voted

Prepaid Medical Insurance, Voluntary Sickness and Hospital Insurance—The House voted to urge the Blue Cross and the Blue Shield to devise plans to offer to the public, particularly the low income segment, comprehensive medical and hospital coverage, including preventive and diagnostic services The Committee on Economics sees no reason why this should not be carried out and so recommends

Approval was voted

Public Medical Care—The House recommended "that the Federal or State government assist the indigent, including all those who are eligible for old age assistance, to obtain medical care by purchasing adequate insurance from existing prepayment hospital and medical plans, provided that all voluntary health insurance programs will be entirely in the hands of the State agency acting in consultation with the State Hospital and Medical Care Council and Regional Hospital and Medical Care authorities set up in health regions within the State" This matter was referred to the chairman of the Subcommittee on Public Medical Care, Dr Stephen R. Monteith, and the Committee on Economics has not as yet received reply The Committee on Economics, however, of its own accord recommends the approval of this resolution

Approval was voted

United Medical Service Ceiling Limits—In regard to a letter addressed to the President of the United Medical Service and referred at the last Council meeting to the Committee on Economics with refer

ence to raising the ceiling limits, the Committee on Economics feels that this should carry an endorsement, first, by each individual county society, and that the Committee on Economics should simply endorse this in principle

Approval was voted

Practice of Medicine by Hospitals and Colleges—The House voted (1) "that the attention of hospitals and teaching institutions be drawn to the opinion of the State Society that such bodies should not practice medicine in any of its branches for pecuniary gain" (Of course writing a letter telling them that is our opinion is very easy to do), (2) "that a conference be held with the deans of medical colleges and representatives of hospitals and teaching institutions to formulate a program which is in the public interest", (3) "that such institutions be requested to take no further action toward entering the practice of medicine until after such a policy has been formulated"

The Committee on Economics have discussed this matter and feel that this is a very, very large order, and we should have a lot of discussion by the Council before this conference is called

After discussion, *it was voted* that the Council defer action on this matter until the Committee on Economics can present a plan regarding such a conference, have an agenda, and discuss what their position would be at such a conference

Ethics—Dr James R. Reuling, chairman, reported "The Council referred to the Committee on Ethics the question of the revision of our Code of Ethics. I have sent to the officers and to the members of the Council the new Code of Ethics as adopted by the American Medical Association and in position alongside of it our corresponding sections. There will be a meeting of the Committee soon I would like very much to have suggestions or recommendations from all councilmen and officers before the meeting of that Committee"

Finance—Dr James R Reuling, chairman, reported as follows "The Committee is endeavoring to prepare the budget for next year with supporting data for each line item in the budget so that the officers, Council, and Trustees may be familiar with all items. As this is an entirely new procedure, considerable difficulty is being encountered and it is felt that again this year the budget may be late for proper study by members of the Council and the Board of Trustees

"It is recommended and I should like the approval of the Council directing the Finance Committee to proceed with the preparation of the 1951 budget early in the year 1950

"If this is approved, it is suggested that all department heads be instructed to cooperate in order that the budget for the following year, 1951, will be ready and in the hands of the Council and Trustees immediately after the close of the 1950 Annual Meeting"

Approval was voted

Publication.—Dr George W Kosmak, chairman, reported that the Committee met on September 7, and the publication date of the *Directory* was discussed. The revision of the form of the *Directory* was referred to a special subcommittee to report at the next Committee meeting He called attention to the prompt issuance of Part II of the September 1 issue of the JOURNAL, which contains the minutes of the 1949 House of Delegates meeting

Public Health and Education.—Dr Theodore J Curphey, chairman, reported that he had attended [illegible] of his various subcommittees and arranged for postgraduate instruction and teaching days for several counties

Subcommittee on Cancer—Dr George Adie, chairman, reported that the Subcommittee recommended preparation of a plan for formation of detection centers, in conjunction with the State Department of Health The Department of Health will undertake its publication, but the Subcommittee felt the State Society should pay part of the printing expense

It was voted that the $200 for the publication of this cancer bulletin be expended from the budget of the Committee on Public Health and Education (and if there is not sufficient money remaining in their budget that they so report at the next meeting of the Council)

He also reported that a plan for the revision of the Cancer Manual was being discussed

Medical Film Review—Dr Curphey reported that there was a meeting of the Medical Film Review Board in Albany on August 2 with Dr Larimore of the State Health Department, at which Dr Hughes, Dr Norris, and Dr David S Ruhe, the director of the Film Review Board of the Association of American Medical Colleges, were present Dr Norris, chairman of the Subcommittee, makes the following recommendations "I would recommend that this board be made up of a member from Buffalo, Rochester, Syracuse, Albany, and Metropolitan New York The function of this board would be to establish policy, both regarding selection of films and promotion It is suggested that each of these men would be chairman of a local Film Review Board, the total membership of which would come from the town in which he was located and the composition of which would be determined by him The function of each local committee would be to review the titles already in our present catalog in one or two specialties and to select from this list those films which warrant reviewing, and to review those films, preparing a report and their evaluation These reports would form the basis for future selection of films for the library and for a descriptive catalog New films, as they appear, would be similarly reviewed We would suggest that Dr David S Ruhe, director of the Film Review Board of the Association of American Medical Colleges and Dr Granville Larimore be made advisory members of this committee" Your Chairman heartily endorses this suggestion.

It was voted that Dr Ruhe and Dr Larimore be made advisory members of this Subcommittee

Rehabilitation and Physical Medicine—Dr Curphey reported that there was a meeting of the Subcommittee on September 1, 1949, at which Dr Morton L Levin and staff from the State Health Department presented an outline of the proposed program for cerebral palsy

Following a general discussion, it was resolved that we endorse in principle the program presented by the State Health Department, but feel that, in the long-range plan, the most important facet is that of adequate training of physicians and ancillary personnel and that such training should be on a broad base with experience in both in- and outpatient facilities, taking into consideration the physical, psychologic, social, and educational problems, and that another important facet is general education of the medical profession, both general practitioners and specialists, in the problems of cerebral palsy, so that they will be familiar with the handling and proper channeling of these patients This Subcommittee will try to carry on such a program within the framework of the State Medical Society

Further discussion centered around the organization of primary and secondary treatment centers It was resolved that when the investigation, which is now being made by the State Health Department, is completed, this Subcommittee will review the procedures and try to formulate basic principles that should be followed in primary and secondary treatment centers

It was recommended that a Subcommittee of the Subcommittee on Rehabilitation and Physical Medicine be formed and that it be designated as Subcommittee on Cerebral Palsy and consist of Dr George G Deaver, chairman, with Dr Alfred Lane and Dr Austin J Canning This committee has been charged with studying the Cerebral Palsy Program of the State Health Department and it is expected to report at the next meeting

Approval was voted

It was further resolved that the Council of the Medical Society of the State of New York be requested to give the Subcommittee on Rehabilitation as much of the teaching day as possible at the next meeting of the Medical Society of the State of New York so that it could put on a dynamic clinical demonstration for both general practitioners and specialists to show procedures that can be carried out in their own practices in the management of the chronically ill and disabled—paraplegics, hemiplegics, amputees, neurologic conditions, old cases of poliomyelitis, etc

Approval was voted

The Subcommittee further requested that the NEW YORK STATE JOURNAL OF MEDICINE publish a series of editorials highlighting the problem of rehabilitation

This was referred to the Publication Committee

It was finally resolved at the request of the State Health Department that the Subcommittee urge the cooperation of the profession in following the mandate of reporting all cerebral palsy cases, feeling that it would be of great benefit both to the public and to the profession

This was referred to the Publication Committee

Diabetes—Dr Curphey presented a communication to be sent to secretaries of all county medical societies which would serve to supplement with concrete suggestion a recent communication sent to our county medical societies by the American Diabetes Association, inviting each of these to take an active part in the Diabetes Detection Drive (D D D) which started its year-round program during Diabetes Week, October 10 to 16 The committee is anxious that our own State make a showing in the national picture befitting its prestige

After discussion, *it was voted* that the county medical societies be officially apprised of the action of the State Society approving of the plan, and also the approval of the State Society regarding the plan for diabetes teaching programs

Blood Banks—Dr Curphey stated "Your Subcommittee on Blood Banks had a meeting last night at the Roosevelt Hotel in which certain recommendations were made It is felt that the State Society should give its support to the revised Westchester Plan, in which cooperation is expected between the county medical society and the Red Cross It was felt that that would in itself represent the sort of pilot plan to take care of the problems of a large suburban county

"The Subcommittee also felt that, as 50 per cent of the population of the State resided in rural areas, a comparable experiment might be made in Glens Falls, a fairly typical sampling of the average rural area, and that the experiment be differed somewhat in that instead of having the avowed cooperation of the Red Cross they develop the program purely on a local basis without aid from the Red Cross

Approval was voted

Program of the New York State Academy of General Practice—Dr Curphey stated that Dr I . Brightman requested "endorsement on the part of the State Medical Society of the program that is being put on by the New York State Academy of General Practice, which represents the first annual meeting of this group Dr William Buecheler of Syracuse is the chairman this year He has organized this program, and Dr Brightman assures me will be good as outstanding men are going to speak The State Department of Health is willing to approve, provided the Medical Society gives its approval first"

Approval was voted

Arrangements for Teaching Day at Next Annual Meeting—"In accordance with the resolution of the House of Delegates charging this Committee join with the Subcommittee on Problems of Alcoholism and the State of New York Department of Health your chairman has been in communication with Dr Milton G Potter, chairman of the Committee on Problems of Alcoholism (a committee of the House of Delegates) for the purpose of arranging a symposium Dr Potter in conference with Dr Brigham of the New York State Department of Health has agreed that a panel discussion on "Chronic Alcoholism as a Medical Problem" instead of a symposium would promote more interest and discussion at the 1950 Teaching Day"

Public Relations—Dr Floyd S Winslow, chairman, reported activities and immediate objectives

Veterans Administration, Liaison with the—Dr Anderton reported for Dr Bauckus A joint meeting of the Committee on Liaison with Veterans Administration and the Board of Directors of Veterans Medical Service Plan of New York, Inc , was held September 7, 1949 Dr J C Harding and Dr Jacques of the Veterans Administration Washington Office were present

The present contract with Veterans Administration expires October 1, 1949, and a new contract eliminating the services of coordinators, sent by Dr Magnusen of the VA offices, was discussed

It was the feeling of the group that coordinators were necessary for the proper control and administration of the plan, and at a previous meeting of the Board a motion was adopted that the continuance of coordinators be included in any contract signed

After discussion, it was agreed that the coordinators were to be retained on a part-time basis at a salary to assure the services of high type men

Motion was made, seconded and carried that the president of Veterans Medical Service Plan be authorized to take up the matter of remuneration and time of service with the coordinators and that the final determination be left to him

The matter of a change in the wording of the fee schedule pertaining to physiotherapists was discussed The point of argument was that Veterans Administration desired to pay physiotherapist technicians direct rather than through the doctor It was felt that this change would be advisable and on motion seconded and carried the president was given authority to make the necessary changes in the contract relative to the payment of physiotherapists

It was voted to approve the report

Workmen's Compensation.—Dr J Stanley Kenney, chairman, reported on the activities of the Committee

NECROLOGY

Donato Vincent Catalano, M.D, of West Brighton, Staten Island, died on October 16 at his home after a long illness, at the age of fifty-nine Dr Catalano received his medical degree from the Jefferson Medical College in Philadelphia, Pennsylvania, in 1915 During World War I he served in France as a captain in the Army Medical Corps Active in civic work on Staten Island for the last fifteen years, Dr Catalano was a former president of the medical board of St Vincent's Hospital, West New Brighton, chief of its obstetric staff, and a member of its committee on surgery He was also attending physician in obstetrics and gynecology at Richmond Memorial Hospital at Prince Bay

Dr Catalano was a former president of the Richmond County Medical Society, a Diplomate of the American Board of Obstetrics and Gynecology, a Fellow of the American College of Surgeons and the New York Academy of Medicine, and a member of the Richmond County and New York State Medical Societies and the American Medical Association

Max N Cohnreich, M D, of New York City, died suddenly on October 8 at the age of sixty-six A native of Germany, Dr Cohnreich received his medical degree from the University of Berlin in 1908 and practiced medicine in Berlin until 1936 For the past fourteen years, Dr Cohnreich had practiced in the Bronx and in 1948 marked the completion of forty years of medical practice After Dr Cohnreich arrived in the United States, he completed three years of postgraduate study at Beth-Israel Hospital. He was a member of the Rudolf Virchow Medical Society of New York City

Edward Martin Cohe, Jr, M.D, of New York City, died on October 22 at his home at the age of seventy Dr Cohe was graduated from the College of Physicians and Surgeons, Columbia University, in 1905 During World War I he served as a colonel in the Army Medical Corps Dr Cohe, who had practiced in New York City for more than forty years, was consultant in gynecology at City and Midtown Hospitals and had been attending gynecologist at the West Side Hospital. A Fellow of the American College of Surgeons, he was a member of the New York Academy of Medicine, the New York County and State Medical Societies, and the American Medical Association

Clarence D'Azavado Daniels, M.D, of Meridian, died on October 13 at the age of sixty-three Dr Daniels received his medical degree from the University of Pennsylvania College of Medicine in 1908 and had been an instructor there before coming to Meridian to start his practice eleven years ago He was a member of the Cayuga County and New York State Medical Societies and the American Medical Association

Robert Tilden Frank, M.D, of New York City, died on October 15 at Doctors Hospital after a short illness, at the age of seventy-four Dr Frank was graduated from the College of Physicians and Surgeons, Columbia University, in 1900, and then took postgraduate studies in Berlin, Germany During World War I he served in France as a captain in the Army Medical Corps From 1920 to 1925 he was attending gynecologist at the University and General Hospitals in Denver, Colorado and an associate in cancer research and associate professor of gynecology at the University of Colorado

In 1906 Dr Frank began his long connection with Mount Sinai Hospital, New York City, as an adjunct gynecologist He became an associate in 1912 and returned there in 1925 as an attending gynecologist From 1937 until his death, he was consulting gynecologist at the hospital Dr Frank was the founder, and, from 1925 to 1944, the director of the endocrine research laboratory at Mount Sinai He was the author of several textbooks on gynecology and endocrinology and of more than 200 scientific papers in the field

Dr Frank was a Diplomate of the American Board of Obstetrics and Gynecology, a Fellow of the American College of Surgeons, and a member of the American Gynecological Society, the New York Academy of Medicine, the New York Obstetrical Society, the New York County and State Medical Societies, and the American Medical Association

John Francis McGrath, M.D, of New York City, died October 15 at St Vincent's Hospital after an illness of three days, at the age of sixty-three. Dr McGrath was graduated from the Cornell University Medical College in 1908 and served his internship at Bellevue Hospital Dr McGrath, who had practiced in New York City for forty years, had been a member of the staff of St Vincent's Hospital for that period of time and was director of obstetrics and gynecology there at the time of his death He was also associate in obstetrics and gynecology at New York Hospital

For thirty years, since 1919, Dr McGrath had been a member of the faculty of Cornell University Medical College, where he was assistant professor of obstetrics and gynecology at his death A Diplomate of the American Board of Obstetrics and Gynecology, Dr McGrath was a Fellow of the American College of Surgeons and a member of the Harvey Society, the Alumni of Bellevue Hospital, the New York Academy of Medicine, the New York Medical-Surgical Society, the New York County and State Medical Societies, and the American Medical Association

Abraham J Rongy, M.D, of New York City, died on October 10 at Mount Sinai Hospital after an illness of two days, at the age of seventy-one. A native of Vilna, Russia, Dr Rongy came to the United States when he was fifteen. He received his medical degree from the Long Island College Hospital in 1899 and interned there the following year Dr Rongy was a founder of the Lebanon Hospital in the Bronx, where he was a staff member and consultant for fifty years Last January, he was one of five physicians with a record of fifty years service at Lebanon who were awarded engraved plaques by the hospital s board of trustees

Dr Rongy was also a founder of the Jewish Maternity Hospital, a consulting gynecologist for the

MEDICAL NEWS

Academy of Medicine Holds Graduate Fortnight

"ADVANCES in Diagnostic Methods" was the theme of the twenty-second annual Graduate Fortnight of the New York Academy of Medicine, held from October 10 to 21 at the Academy building in New York City. During the two-week program of lectures, panels, hospital conferences, and motion pictures, several hundred outstanding physicians from different parts of the country and many of the Fellows of the Academy of Medicine participated in an intensive study and review of the new technics and procedures by which disease conditions can be diagnosed more promptly.

An innovation this year was an exhibition and demonstration of x-rays by means of television. The "Television of the Interpretation of Roentgenograms" was arranged by Dr. Ross Golden and Dr. Robert P. Ball. A special exhibit of books dealing with advances in diagnostic methods was arranged for the Fortnight by the Library.

The Graduate Fortnight program was organized by a subcommittee of the Committee on Medical Education, of which Dr. Louis Soffer is chairman and Dr. Mahlon Ashford, secretary. Hospital conferences were arranged by a subcommittee headed by Dr. Conduct W. Cutler, Jr. The scientific exhibit was under the direction of Dr. Alfred Angrist, and panel discussions under the chairmanship of Dr. Lloyd F. Craver.

Award Grants for Medical Research

GRANTS of $2,056,426 have been awarded by the National Institutes of Health to provide continued support for medical and allied research projects at non-Federal institutions. A total of 217 projects will be supported at 94 institutions located in 31 states, the District of Columbia, Alaska, and four foreign countries.

The projects are designed to provide new scientific data on a wide variety of human ailments. They include studies of deafness and speech defects, peptic ulcers, the common cold, and the relation of the endocrine glands to aging. They also include studies of the changes induced in the living cell by irradiation, the longevity and behavior of pathogenic bacteria in frozen food, and the viability of enteric bacteria in sea water and factors controlling the fate of sewage after discharge in the sea.

Continuation grants approved in New York State include the following:

American Public Health Association, New York City, Reginald M. Atwater, $27,972, for research in the evaluation of local health services.

Columbia University, New York City: Hattie E. Alexander, $13,651, comparison of efficacy of specific therapeutic agents in whooping cough, Rhode W. Benham, $4,644, effect of nutrition on morphology of dermatophytes, Benjamin N. Berg, $4,482, to study the effects of pantothenic acid deficiency alone and in combination with other partial deficiencies on the duodenal mucosa, Alfred Gilman, $10,692, studies on renal physiology with special reference to the effect of drugs on renal function, Stephen S. Hudack, $10,800, studies in articular replacement, John S. Lockwood, $5,189, studies on lysozyme in ulcerative disease, David Shemin, $7,398, transamination and the intermediary metabolism of amino acid studied with the isotope technic, and H. B. Van Dyke, $13,176, metabolic fate and localization of representative barbiturates, diphenylhydantoin and trimethadione by the use of isotopes.

Cornell University Medical College, New York City: Thomas P. Almy, $3,500, clinical evaluation of the results of psychotherapy in duodenal ulcer, William DeWitt Andrus, $7,776, studies on the etiology of ulcerative colitis, Herbert Conway, $4,987, studies on the rehabilitation of children with speech defects persistent after primary surgery for cleft palate, John G. Kidd and Lewis D. Stevenson, $5,000, analysis of encephalomyelitis, other studies in neuropathology, Milton I. Levine, $8,404, study of adolescent children inoculated with BCG in early infancy, Mary Hewitt Loveless, $4,860, the relation of protein binding and other induced variables to the activity of antimicrobial agents as reflected by host-parasite relationships in vivo, and Carl H. Smith, $11,340, pathogenesis and treatment of Mediterranean (Cooley's) anemia.

Long Island College of Medicine, Brooklyn, Peter Gruenwald, $7,138, pathology and causes of death during fetal and neonatal periods.

Mount Sinai Hospital, New York City: Harry Sobotka, $6,000, thermophil enzymes and proteins.

New York State Department of Health, Albany: F. Wellington Gilcreas, $6,425, study of standard methods for the chemical examination of sewage, H. McLeod Riggins, $37,128, comparative value of streptomycin versus dihydrostreptomycin in tuberculosis, combined chemotherapy of tuberculosis, and the toxic and therapeutic effects of neomycin, alone and with PAS.

New York University, New York City: Henry Doubilet, $11,880, relation of biliary-pancreatic reflux to diseases of the pancreas and biliary tract.

New York University, Bellevue Medical Center, New York City: Heinz L. Luschinsky, $5,184, the enzymatic activity of the placenta in normal pregnancy and toxemia, Alfred Marshak, $39,042, metabolic studies in relation to chemotherapy of tuberculosis, Severo Ochoa, $10,000, study of enzyme systems involved in biologic oxidations and syntheses.

Queens College, Flushing: A. H. Blatt, $9,450, synthesis of pentaquin with labeled atoms.

St. Clare's Hospital, New York City: Max A. Goldzieher and William Bryant Rawls, $9,940, the relation of the endocrine glands to aging.

Syracuse University, Syracuse: Paul A. Bunn, $9,914, to determine the advantages of using the rabbit's eye as a tissue to study antibacterial activity of tuberculostatic agents.

University of Rochester, Rochester: Edward F. Adolph, $12,960, adaptations of animals to cold and to dehydration, George H. Ramsay, $10,548, iodinated organic compounds as contrast media for radiographic diagnoses.

New York University Medical Alumni Day

TO MARK the Alumni Day at the New York University College of Medicine, a unit of the New York University-Bellevue Medical Center, on November 11, a program of six papers was presented

Speakers included Dr John H Mulholland, professor of surgery, "Present Status of Vagotomy in Peptic Ulcer", Dr Morris Herman, professor of surgery, "Present Status of Psychotherapy in General Practice", Dr William L Watson, associate professor of surgery, "Present Status of Special Diagnostic Tests in Carcinoma", Dr Arthur DeGraff professor of therapeutics, "Anticoagulants in the Treatment of Myocardial Infarctions and Other Cardiac Conditions", Dr William E Studdiford, professor of obstetrics and gynecology, "Present Status of Newer Technics on Management of Labor," and Dr Harrison Stanford Martland, professor of forensic medicine, "The Teaching of Legal Medicine and the Proposed Institute of Forensic Medicine at New York University"

MEDICALLY SPEAKING—

Award for Essay on Hippocrates—A $100 government savings bond will be awarded for the best essay on "The Meaning of Hippocrates in the Medical World Today" by the United States Chapter of the International College of Surgeons, according to a recent announcement Entries, which will not be restricted to any certain number of words, must be postmarked not later than March 1, 1950 The contest is being held in connection with the celebration of Hippocrates Day by the International College of Surgeons in Chicago, held October 23, 1949 Entries may be sent to Essay Contest, care of the International College of Surgeons, 1516 Lake Shore Drive, Chicago 10, Illinois

Nursing Population—In a booklet released by the American Nurses' Association, certain interesting information is presented An inventory of professional registered nurses in 1949 disclosed that the population per active professional registered nurse is shown to be five states, only one nurse for 95 to 1,997 population, while five other states had one nurse for every 270 to 324 residents The number of professional nurses in hospitals and schools of nursing increased sixteen per cent from 1947 to 1948 In addition, the number of professional nurses employed by government agencies rose in 1949, compared with the previous year On the other hand, enrollment of student nurses on January 1, 1949, totaled 88,817, a drop of about three per cent from the 91,643 students enrolled on January 1, 1948 The 1949 enrollment is about the same as the total on January 1, 1941

Lectures on Industrial Medicine—The Faculty of Medicine of Columbia University, New York City, has announced a series of lectures on industrial medicine, which are being given on Saturday mornings from 9 00 to 10 00 A M in Amphitheater A, College of Physicians and Surgeons, 630 West 168th Street The lecturers are members of the staff of the Industrial Hygiene Division of the School of Public Health Interested members of the medical profession are invited to attend. There is no formal registration and no tuition fee

Lectures already presented include

September 24—"History of Industrial Medicine"
October 1—"Scope Objectives, and Practice of Industrial Medicine"
October 8—Industrial Health in Relation to Public Health "Hygiene of the Environment"
October 15—Industrial Toxicology—General Considerations"
October 22—"Toxic Metals"
October 29—Toxic Solvents"
November 5—"Toxic Dusts"
November 12—"Toxic Gases"

Lectures remaining on the schedule include

November 19—"Emotional Problems in Industrial Medicine"
November 26—"Workmen's Compensation"
December 3—"Elementary Nuclear Physics"
December 10—"Health Hazards Due to Radiation"

Washington County

The Washington County Medical Society held its annual meeting on October 11 The following officers were elected for the coming year Dr Joseph Feingold, Fort Edward, president, Dr Leo Thume, Fort Ann, vice-president, Dr Denver M Vickers, Cambridge, secretary, and Dr Charles A. Prescott, Hudson Falls, treasurer Dr John Sumner presented the presidential address on "Experience with Aureomycin," and Dr Francis W Dodge, Albany, spoke on "Diagnosis and Treatment of Diseases of the Hip"

Wyoming County

On October 12 a regular meeting of the Wyoming County Medical Society was held in Warsaw The following officers were elected for the coming year Dr Bruno J Tryka, Perry, president, Dr S T Williams, Attica, vice-president, and Dr P A. Burgeson, Warsaw, secretary-treasurer

CORRESPONDENCE

TOXIC DRUGS AND ACCIDENTS

To the Editor

A study is being made in the Department of Pharmacology and Toxicology of the University of Rochester School of Medicine and Dentistry, under the direction of Dr Harold Hodge, to determine to what extent the effects of therapeutic drugs and exposure to toxic chemicals contribute to the high death and disability rates due to accidents

This study is part of a wider consideration of the medical aspects of accident control and is concerned particularly with the problem of injuries and poisonings which occur in homes and on farms There is special emphasis on the etiology of accidents to children between the ages of one and twenty years, since accidents are the leading cause of death in this age group, and second only to congenital malformations as a cause of permanent disability

In dealing with industrial and traffic accidents, some degree of mechanical and legal control is possible In homes and on farms, where the accident rate is highest, the most authoritative influence is that of the practicing physician

It has been shown statistically that about 20 per cent of the total population have most of the accidents There is also considerable evidence to show that many of these accident-prone individuals are suffering from physical or emotional disorders which can be diagnosed and treated clinically The baffling problem of accident control may well find its solution in the offices of private practitioners

A request is being made to doctors to help in the study described above The immediate need is for case histories of the following type

1 Records of patients who have had accidents while under the effects of medications such as antihistaminics, anticonvulsants, barbiturates, sulfa drugs, insulin, bromide, atropine, and procaine hydrochloride

2 Records of patients who have had accidents after exposure to toxic chemicals such as carbon tetrachloride, naphtha, etc

3 Records of patients who have suffered kidney or liver damage after exposure to toxic chemicals There is special interest in case histories of such damage after exposure to carbon tetrachloride used for dry cleaning, as a solvent, or as a watermark detector by stamp collectors

4 Records of patients who have had repeated small or major injuries because of some physical disorder such as limited hearing, defective vision, orthopedic impairment, epilepsy (slight petit mal or psychomotor attacks), heart failure, diabetes

Assistance in obtaining this material will be greatly appreciated Please address all communications to

Marion Gleason
Department of Pharmacology and Toxicology
University of Rochester School of Medicine and Dentistry
200 Crittenden Boulevard
Rochester, New York

NOTE The foregoing letter appeared in the July 2 1949, issue of the *Journal of the American Medical Association* and is reprinted for the attention of physicians in New York State.

CHRONIC BRUCELLOSIS

To the Editor

Dr J A Mishkin's well-documented report, "Chronic Brucellosis Complicated by Severe Pancytopenia," published in the NEW YORK STATE JOURNAL OF MEDICINE, September 15, 1949, deserves comment because of the importance of bringing this aspect of brucellosis to the attention of the medical profession and because of the statement that there is no mention in the current literature or texts of a marked depression of the hemopoietic system

Whereas cases such as the one reported by Dr Mishkin undoubtedly are not common, they have been observed. In my book, *Brucellosis (Undulant Fever)—Clinical and Subclinical*, Paul B Hoeber, Inc , 1941, I stated on page 118 "Anemia is found in a large percentage of cases of acute or chronic brucellosis The degree of depression of hemoglobin and red blood cells varies greatly without much regard to the severity of the infection Very low hemoglobin readings are occasionally encountered Red blood cells are often reduced in number to 2,500,000 or fewer Hemoglobin and red cells are reduced proportionately The picture is usually one of secondary anemia of other origin Occasionally the anemia is profound *Rarely it closely resembles pernicious anemia from which it must be carefully distinguished*" [The italics were used]

Leucopenia and relative lymphocytosis were discussed Calder, Steen, and Baker [Blood Studies in Brucellosis, *J A M A* 112 1893, (1939)] were quoted as to their extensive observations They had found slow clotting time in one third of cases, with normal platelet counts, in agreement with my own observations In four of my patients slow clotting time was reversed following specific therapy of the Brucella infection Purpura was discussed

Blood changes in brucellosis are discussed more extensively in the revised edition of my book, now in press

Dr Mishkin's case, although not culturally proved, probably was one of active Brucella infection The observations made and the results achieved have added confirmation to the oft-made statement that brucellosis may cause or simulate a wide variety of clinical and pathologic manifestations often ascribed to other origin

HAROLD J HARRIS, M D

New York City
September 28, 1949

Reply by Dr Mishkin

To the Editor

I wish to thank Dr Harold J Harris for his worthy comments of my article, "Chronic Brucellosis Complicated by Severe Pancytopenia"

In recent years there have been more frequent articles referring to the widespread manifestations of Brucella infections, to the many organic systems which may be involved in brucellosis However, except for brief mention of the secondary anemia, leucopenia, and relative lymphocytosis, very little has been reported concerning the more severe types of blood dyscrasias which may be seen with this disease process

In the case reported by me, the marked depression of the hemopoietic system was so profound that the blood picture simulated that seen in aplastic anemia The hemoglobin ranged between 30 to 44 per cent Sahli and the red blood count between 2,160,000 to 2,500,000 The white blood cells averaged 2,300 per cu mm and the platelets 86,000 This picture lasted for about one month in spite of repeated whole blood transfusions, iron orally, and liver extract intramuscularly It was not until the infectious process was controlled with streptomycin that the blood picture reverted to normal Clotting and bleeding times and clot retraction were within normal limits Lack of space did not allow valuable tables, which indicated the progressive changes in the blood picture during the course of the disease, to be included in the article

It should be emphasized at this time that the modern concept of the active treatment of Brucella infections places prime importance on the newer antibiotics, aureomycin and chloramphenicol

J A Mishkin, M D

BOOKS REVIEWED

The Case Against Socialized Medicine A Constructive Analysis of the Attempt to Collectivize American Medicine By Lawrence Sullivan. Second edition Duodecimo of 54 pages Washington, Statesman Press, 1949 Cloth, $1 50

Visionary bureaucrats, seeking to foist a foreign way of life upon an unsuspecting public and beclouding the outlook of many highly placed in political and other circles, do not hesitate to use questionable interpretations of statistics, advance specious arguments insidiously distorting the truth, and, with a simulated cloak of outraged righteousness, denounce those who seek to prove them wrong, blithely branding as enemies of the people those who wish to keep American medicine American.

Nowhere is this more aptly demonstrated than in Lawrence Sullivan's latest book, *The Case Against Socialized Medicine*

Based on the sworn testimony of witnesses before the committees of the House and Senate, Sullivan's thesis builds up a powerful argument against the monstrous attempt on the part of bureaucrats to bring the American public further into their power With laudable efforts to remain unbiased, the author presents the history of socialized medicine in other lands

His well-documented account clearly shows the dangers ahead for those who prefer the American system of freedom and ordered liberty under law for

"If American medicine can be taken over by the government, then every other activity also may be socialized under a gigantic bureaucracy "

This book is must reading for Americans bred in the traditions of free people who do not want to see medical advances curtailed by endless red tape nor see their country's health sink to a low level "when village doctors are selected like postmasters."

Fantastic? Not at all!

Read *The Case Against Socialized Medicine* by one of Washington's veteran newspapermen and a distinguished magazine and radio reporter and you'll agree with him that

"So long as we keep American medicine out of the bureaucratic shackles, we shall maintain our world leadership in health and welfare But all history tells us that once the bureaucrats take over, freedom is smothered and progress stops."

MORRIS WEINTROB

The Biological Standardization of the Vitamins By Katharine H Coward, D Sc Second edition Octavo of 224 pages, illustrated. Baltimore, Williams & Wilkins Co , 1947 Cloth, $5 00

This clear and concise handbook on biologic standardization of the vitamins should be a valuable reference book for workers in the field of nutrition Technics are simply and adequately described, and methods of computation illustrated by examples Titles and illustrations are well chosen

The closing chapters on statistical methods may prove especially helpful for both theoretical and practical uses

ARTHUR SHAPIRO

The Medical Clinics of North America. Chicago Number January, 1949 Octavo Philadelphia, W B Saunders Co , 1949 Published Bimonthly (six numbers a year) Cloth, $16 net, Paper, $12 net.

This edition of the *Clinics* has excellent reviews, with good bibliography, of dermatomyositis, sarcoidosis, disseminated lupus erythematosus, exfoliative dermatitis, and the herpes problem

ANDREW BABEY

The Basis of Chemotherapy By Thomas S Work, Ph.D , and Elizabeth Work, Ph.D Octavo of 435 pages, illustrated. New York, Interscience Pubs , 1948 Cloth, $6 50

The authors of this book have endeavored to bring the microbiologist, bacteriologist, biochemist, and organic chemist up to date.

The book is quite comprehensive and is a fine starting point for such as require the basic data for research.

3 Useful Cardiac Drugs

① Thesodate — Brewer IN ANGINA PECTORIS

(Theobromine Sodium Acetate 7½ gr enteric coated)

Thesodate has been proven effective in increasing the capacity for work in individuals suffering from coronary artery disease One Thesodate tablet four times a day (after meals and at bedtime) helps to maintain improved heart action and increased coronary artery circulation

② Enkide — Brewer IN LUETIC HEART DISEASE

(Potassium Iodide one gram or half gram enteric coated)

Enkide is useful as an adjuvant in tertiary syphilis and wherever potassium iodide therapy is indicated Enkide insures accuracy of dosage, absence of gastric irritation and convenience of administration Patients are more apt to follow prescription directions because of these advantages

③ Amchlor — Brewer IN CARDIAC EDEMA

(Ammonium Chloride one gram enteric coated)

Amchlor cuts in half the number of tablets each patient takes when large amounts of ammonium chloride are prescribed This convenience to the patient helps to insure full and complete use of the entire amount prescribed Amchlor is useful in cardiac edema, hypertension, dysmenorrhea, Meniere s Syndrome, etc

CONSTANT RESEARCH

Invented in 1861, Hanger Artificial Limbs have been constantly improved over the years Today, the Hanger Leg is recognized as one of the world's finest artificial limbs

Hanger Research is continually developing and testing new ideas new methods, and new materials. From these efforts have come many outstanding achievements, adding greatly to the comfort and to the ever increasing utility of the limb Hip control dural light construction, natural action joints, the flexible foot are a few of the many advancements of recent years

The many Hanger companies in many key cities throughout the United States are constantly studying, planning, and developing new improvements to give you an ever better artificial limb

Laxative Modifier of Milk for Constipation in Infants

•

Borcherdt
MALT SOUP EXTRACT
(Liquid)

•

DRI-MALT SOUP EXTRACT
(Powder)

FEATURES

• High proportion of readily fermentable maltose encourages the growth of aciduric bacteria and retards growth of putrefactive organisms.

• Malt Soup Extract stimulates peristalsis

• Water-soluble extractives of choice, malted barley and the added potassium carbonate contribute to the gentle laxative effect.

• Mixture of sugars (maltose-dextrins) means better toleration—no danger of gastrointestinal irritation, excessive fermentation, or diarrhea when used as directed by the physician.

Palatable *Dissolves Readily in Milk*

SUPPLIED Malt Soup Extract—Jars containing 8 fl.oz. and 1 pt. Dri Malt Soup Extract—Jars containing 1 lb

This is how Chic Young, the cartoonist, makes a first rough sketch for the famous strip

Then when each panel in a strip meets his approval, he makes a careful pencil rendering as above.

After this, the pencil rendering is carefully inked in, as you see here

STEP BY STEP . . .

that's the way it's done successfully!

As you can see, Chic Young, who draws the popular "Blondie" comic strip, goes through many steps to arrive at a finished cartoon

And, cartoonist Chic Young, together with millions of other smart Americans, will tell you that the step-by-step method is the easiest, surest way of doing anything worth while

Particularly, saving money

One of the easiest and surest ways to set aside any worth while amount of money is to buy United States Savings Bonds the step-by-step method—

So set aside a regular amount week after week, month after month, year after year Then in 10 short years you will have a mighty nice nest egg tucked away

Get started now Get your Bonds through Payroll Savings or at your bank or post office

AUTOMATIC SAVING IS SURE SAVING—U S SAVINGS BONDS

New concept of control in nasal congestion

Antistine-Privine
NASAL SOLUTION

This new synergistic combination, Antistine to block the congestive action of histamine, and Privine to shrink nasal mucosa, provides prompt, prolonged relief of nasal congestion.

It has been established that "the decongestant action of Antistine-Privine in many instances appears to be more intense and prolonged than from either solution alone."[1]

DOSAGE: 2 to 3 drops in each nostril 3 or 4 times daily

BAXTER

Blood Banking

WITHOUT WASTE

The Baxter method of collecting, storing and administering blood and plasma is a model of simplicity, safety and streamlined efficiency. The closed system, developed and introduced by Baxter, insures sterility. Baxter expendable donor and administration sets make procedures simple, safe, expedites teaching. And now the new Baxter Fuso-Flo stopper solves the aging problem, insuring trouble-free, easy flowing infusions. A demonstration of this complete Baxter program can be arranged without obligation.

For information address MEDICAL EXECUTIVE OFFICER 345 W 50th St., New York City, 19

Chloral hydrate, used in medicine since 1869, is, even today, "the standard hypnotic of its class"[1]

Goodman and Gilman observe that it "is unfortunately neglected today," and that the present widespread use of the barbiturates has " caused the physician to lose sight of the fact that chloral hydrate is still one of the cheapest and most effective hypnotics"[2]

In FELLO-SED, supplementation with calcium bromide and atropine sulfate largely overcomes unwanted side actions, enhances the sedative effect and provides valuable antispasmodic activity It is presented in palatable liquid form

[1]N.N.R., 1947 p 398
[2]Goodman, L. & Gilman, A., The Pharmacological Basis of Therapeutics MacMillan, 1944, pp. 177-8.

Available in 8 fluidounce bottles

Adult Dose. As a sedative. ½ to 1 teaspoonful with water, every 3 or 4 hours or as directed As a hypnotic, 1 to 2 teaspoonfuls or more with water at bedtime, or as directed

FELLO-SED

FORMULA: Each fluidram (4 cc.) contains, in a palatable aromatic vehicle Chloral Hydrate, 0 5 Gm (7½ gr), Calcium Bromide, 0 5 Gm. (7½ gr), Atropine Sulfate, 0 125 mg (1/480 gr)

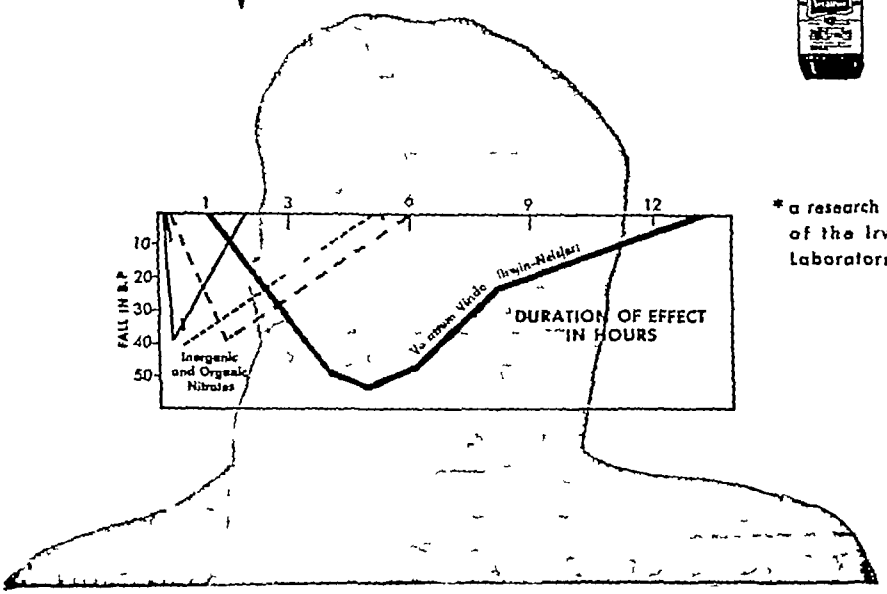
PHYSIOLOGIC FALL

in blood pressure

Of the many drugs commonly used to lower arterial pressure in hypertension, Biologically Standardized *veratrum viride* (in CRAW UNITS*) is the only drug that produces a physiologic fall in blood pressure

Thus, a prominent feature in the integrated response to oral doses of veratrum viride in CRAW UNITS is a reduction in peripheral resistance without compromise of circulation and without disrupting circulatory equilibrium



VERATRITE represents a practical modification of this effective hypotensive drug for everyday management of the mild and moderate cases of essential hypertension

Prolonged action, wide range of therapeutic safety and complete simplicity of administration are specific advantages of Veratrite therapy. Each Veratrite Tabule contains Biologically Standardized *veratrum viride* 3 CRAW UNITS, sodium nitrite 1 grain, phenobarbital ¼ grain

Samples and literature on request.

Announces a

FOUR DAY FRACTURE COURSE
By SIR REGINALD WATSON-JONES of London

Assisted by members of the Committee

Friday, Saturday, Sunday and Monday, February 17, 18, 19, and 20, 1950 Immediately following the meeting of the American Academy of Orthopaedic Surgeons

Lenox Hill Hospital Auditorium, New York City

Registration limited to 350—Cost of Course $50

Applications will be accepted from veterans under the G I Bill if Course receives approval of Veterans Administration Apply to

Dr William H Cassebaum,
112 East 74th Street, New York City

BURO-SOL POWDER

Readily soluble in water
Buro-sol Solution is therapeutically equivalant to Burows Solution (Liq Al Acet)

The powder is a convenient method of preparing a solution when needed.

Compresses saturated in Buro-sol Solution prevent a sudden change in the pH value of the skin and will neutralize alkalinity

Applied on inflamed surfaces, weeping eczema, the inflammatory process will be mitigated

DOAK CO., INC.
Cleveland, Ohio
NY 12-49

Appointment for anointment

Advise the arthritic to have an appointment with himself twice daily—

to apply ARTHRALGEN®

arthralgesic unguent

to painful joint and muscle areas Relief from musculoskeletal discomfort after a single application is gratifyingly rapid, in a matter of minutes, and is of long duration, extending up to six hours following concomitant exposure of the affected parts to moist or dry heat

Why does Arthralgen work so well? Its special formula advantageously blends the old and the new in local therapy Rubefaction due to thymol and menthol plus analgesia due to methyl salicylate are synergistically combined with the unique vasodilating action of methacholine chloride Arthralgen dilates both capillaries and arterioles. The resulting active hyperemia tends to counteract the vasospasm found in articular and non-articular rheumatism, relieves pain and discomfort and brings a welcome feeling of deep warmth and relaxation All this is facilitated by Arthralgen's special ointment base containing selected wetting agents which enhance surface penetration and facilitate speedy effectiveness of the active ingredients.

Arthralgen is beneficial in the treatment of arthralgias, myalgias and neuralgias—sprains, lumbago, synovitis, bursitis, neuritis and myositis. In chronic arthritis, Arthralgen is a valuable topical adjunct to systemic therapy

Arthralgen, Arthralgesic Unguent, contains 0.25% methacholine chloride, 1% thymol, 10% menthol and 15% methyl salicylate; available in 1 ounce tubes and half pound jars

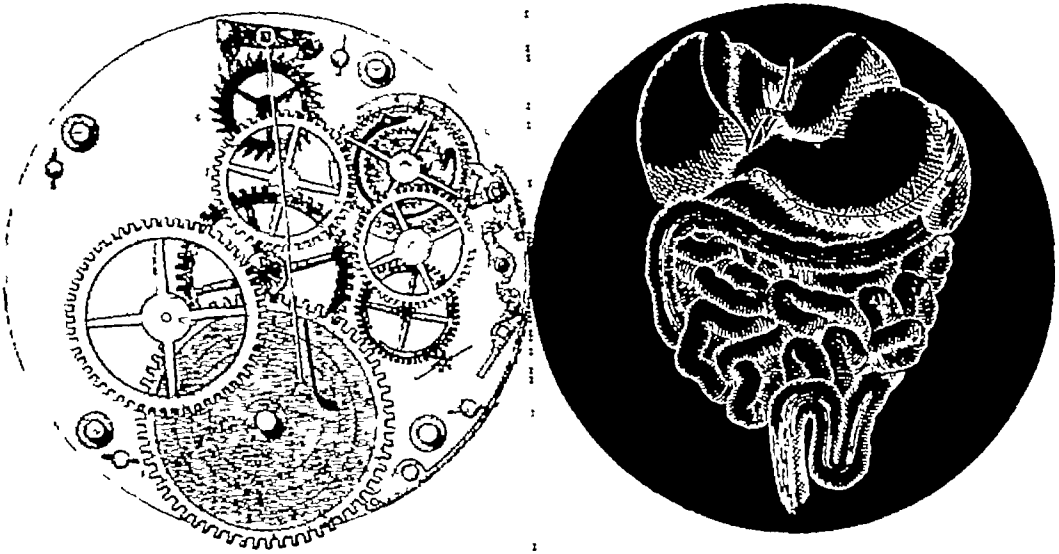
for Eczema

Allays itching
Reduces hyperemia
Promotes formation of normal skin



LENIGALLOL
(triacetylpyrogallol)

Council Accepted

For the usual case of eczema, prescribe Lenigallol 6% in an ointment base, with or without zinc oxide. Stronger applications may be required for more resistant eczema and athletes' foot.

BILHUBER-KNOLL CORP - - ORANGE, NEW JERSEY

Facilitating Bowel Movement

Agoral* plain

WARNER

AGORAL* PLAIN 'WARNER' is a specially processed, thoroughly homogenized emulsion of mineral oil, an agar gel, tragacanth, acacia, and egg albumen The homogenized emulsion mixes freely with the intestinal contents helping to form and maintain a soft mass In addition, AGORAL* PLAIN provides lubrication which facilitates passage of the feces through the intestinal canal

AGORAL* PLAIN is particularly useful in cases in which intestinal irritants or cathartics are contraindicated or not required AGORAL* PLAIN has a mild, non irritating, gentle action Anal seepage, a usual occurrence with mineral oil and mineral oil emulsions, does not occur with AGORAL* PLAIN

AGORAL* PLAIN has a pleasing taste and may be taken undiluted or mixed with water, milk, or fruit juices

AGORAL* PLAIN is indicated in all conditions where acute or chronic constipation must be corrected without strain—pregnancy, cardiovascular diseases, old age, and postsurgical convalescence

AGORAL* PLAIN 'WARNER' is available in bottles of 16 fluidounces

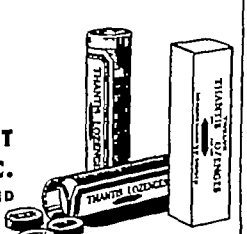
TIME FOR



Thantis LOZENGES

For throat irritations Thantis * Lozenges provide effective relief Thantis Lozenges are especially beneficial in soothing these conditions because they are both antiseptic and anesthetic for mucous membranes of the throat and mouth These effects are due to the two active medicinal agents, 'Merodicein'* an antiseptic of low toxicity, and Saligenin, a mild local anesthetic When 'Thantis Lozenges are dissolved in the mouth, the two ingredients dissolve slowly, providing prolonged medication of the throat.

Each lozenge contains 'Merodicein (H W & D brand of monohydroxymercuridiiodoresorcinsulfonphthalein-sodium) 1/8 grain, Saligenin (orthohydroxybenzyl alcohol, H W & D) 1 grain

Supplied in vials of 12 lozenges in individual cartons packed in dozens

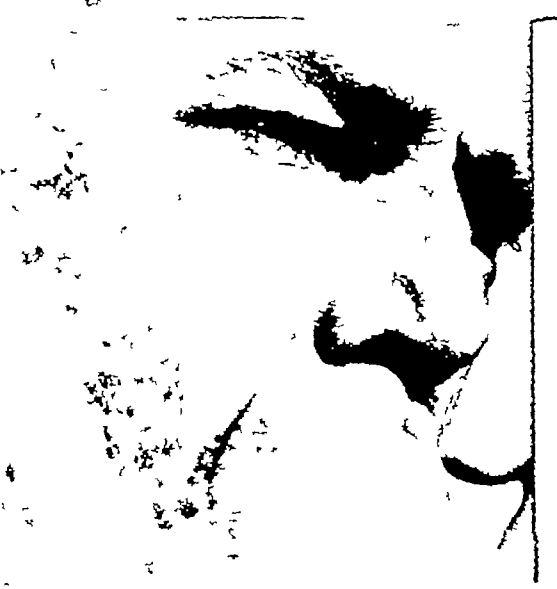
Folic Acid

Folic acid, in either free or conjugated form, is a normal constituent of the tissues of the body and is usually present in the gastrointestinal tract. Not only are the glossitis and enteritis of sprue dramatically relieved by folic acid but the blood picture is also simultaneously improved. *Lederle* has been extremely active in conducting research in the field of nutrition, both in animals and man, and it is anticipated that the orientation of folic acid with respect to a number of other nutritional factors — including the anti-pernicious anemia factor and the animal protein factor — will soon be made clear

LEDERLE LABORATORIES DIVISION *American Cyanamid company* 30 Rockefeller Plaza, New York 20 N Y

why acne clears up so rapidly when you prescribe



Acnomel

ACNOMEL's rapid action is due, chiefly, to its remarkable vehicle This special vehicle, which embodies an entirely new principle, assures the effectiveness of ACNOMEL's time-tested active agents It has all the virtues of an oil-in-water emulsion, yet it is entirely free from wax, oil, or grease ACNOMEL is stable, grease-free, flesh-tinted It contains resorcinol, 2%, and sulfur, 8% Available, on prescription only, in specially-lined 1½ oz tubes

Smith, Kline & French Laboratories, Philadelphia

Acnomel *a significant advance, clinical and cosmetic,* **in acne therapy**

ow, better relief with...

a distinctive, new, non-narcotic antitussive-expectorant

At last, something really new in cough syrups something completely rational clinically sound Robitussin 'Robins' Robitussin employs glyceryl guaiacolate and desoxyephedrine hydrochloride, in a palatable aromatic syrup vehicle

Glyceryl guaiacolate has proven an effective aid to expectoration, and a cough ameliorator with prolonged action, through its increase in and thinning of respiratory tract fluid,[1 2 3] yet it has no ill effect upon digestion [1]

Desoxyephedrine's sympathomimetic action is also well recognized[4 5 6] by relaxing spasm of the bronchial musculature and helping maintain normal respiratory smooth muscle tone, it greatly minimizes the provocation of cough from spasm [5] At the same time it affords relief from psychic depression or a feeling of fatigue

The syrupy vehicle, with its aromatic volatile oils, has a local demulcent effect Furthermore, it assures patient cooperation by providing a base which makes Robitussin one of the most palatable of all antitussive expectorants.

You will find Robitussin 'Robins' an exceptionally efficient safe, therapeutic tool in the management of cough—for both adults and children

Robitussin

FORMULA Each 5 cc (1 teaspoonful) of Robitussin contains:

Glyceryl Guaiacolate	100 mg
Desoxyephedrine Hydrochloride	1 mg

In a palatable aromatic syrup

DOSAGE Children one-half to one teaspoonful according to age, three or more times daily Adults, one or two teaspoonfuls as necessary every two to three hours

SUPPLIED Pint and gallon bottles.

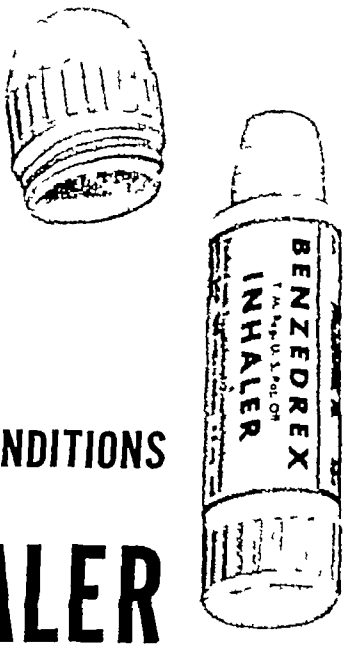
Foresight in pregnancy

PRANONE,* Schering's orally effective corpus luteum preparation makes it possible to prevent many of the mishaps of pregnancy due to corpus luteum deficiency A history of abortion warrants the usage of PRANONE the moment pregnancy is recognized With the appearance of any active signs of threatened abortion, large doses of PROLUTON* (Schering's Progesterone U S P XIII) are indicated.



PRANONE

(Anhydrohydroxy progesterone U.S.P. XIII)

PRANONE can serve as the oral equivalent to PROLUTON administered by injection In addition to maintaining pregnancy in patients with histories of abortions, PRANONE has proved to be efficacious for the relief of dysmenorrhea and premenstrual tension Patients appreciate the effectiveness and convenience of therapy afforded them with PRANONE

Schering CORPORATION BLOOMFIELD, NEW JERSEY

PROVED

UNDER ACTUAL PRACTICING CONDITIONS

BENZEDREX INHALER

SO MUCH BETTER THAT WE HAVE DISCONTINUED BENZEDRINE* INHALER

Our new BENZEDREX INHALER was tested by rhinologists in controlled studies for more than two years Reports were unanimously enthusiastic

Nevertheless, to make absolutely certain that BENZEDREX INHALER was the best volatile vasoconstrictor ever developed we decided to test it with a large segment of the medical profession under actual practicing conditions

We therefore replaced 'Benzedrine' Inhaler with BENZEDREX INHALER in the entire state of California Now, after more than a year's use, California physicians tell us that they and their patients find BENZEDREX INHALER the best inhaler they have ever used

BENZEDREX INHALER has exactly the same agreeable odor as 'Benzedrine' Inhaler, but gives even more effective and prolonged shrinkage, and does NOT produce excitation or wakefulness

* Benzedrine (racemic amphetamine, S.K F) and 'Benzedrex' T M Reg U S Pat Off Each Benzedrex Inhaler is packed with 1 cyclohexyl 2-methylaminopropane, S.K F , 250 mg., and aromatics

powder
inhalation
therapy
for

Now the simplicity and convenience of powder inhalation therapy promises prompt relief in bronchial asthma, thanks to an effective new drug, available as a powder in Aerohalor* Cartridges The drug is *Norisodrine* Sulfate, a sympathomimetic amine with a marked bronchodilating effect

For oral inhalation, the patient uses the Aerohalor®, Abbott's powder inhaler, and a multiple-dose cartridge containing *Norisodrine* Sulfate powder He follows the "smoke it like a pipe" procedure already popularized by the Aerohalor, except that for a single dose he inhales only a small portion of the contents of one cartridge Relief usually follows quickly Effectiveness of the drug has been confirmed by clinical observation [1,2]

When the drug is properly administered, side effects are infrequently encountered and usually are minor in nature However, overdosage can result in disturbing side-effects It is imperative that the physician know and carefully instruct the patient in the methods of administration and precautions to be taken It is recommended that the dosage for each patient be carefully established under the physician's personal supervision Write now for your copy of literature ABBOTT LABORATORIES NORTH CHICAGO ILL.

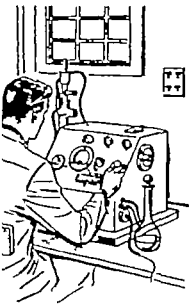
Tactics

Tactics are the art of using or handling available resources to accomplish an end Physicians are accustomed to their daily use in the battle for the lives of patients. In medicine, however, the opposing forces are either inanimate or, as in the case of micro-organisms, without apparent intelligent direction or leadership, finally, as in the case of neoplasms, purposeless malignancies Physicians deal tactically with these opposing forces of destruction with the patient's economy, his person, and his environment as the battleground. Perhaps only in the field of psychiatry does he employ fully resources other than material

Accustomed by education and practice to the artful employment of increasingly excellent medical tactics against disease in sick people, what is his predicament when the problem calls for the tactical use of available resources vis-à-vis well people, aggregations of well people, with intelligent leadership, well people who would detach the control of his profession from him? Here, indeed, is a predicament, and a serious one

It is probably safe to say that most physicians know little about well people and have wasted little or no time in studying them beyond establishing, for scientific purposes, certain norms. This is not, perhaps, a serious matter, as long as no more is involved than the person-to-person relationships of the individual practice of medicine But it becomes more serious and may be calamitous even, when physicians in aggregate seek to accomplish an end through the intermediary of well persons As a matter of tactics, an aggregation of physicians such as a state medical society should be able, at least theoretically, to develop a technic of using or handling its available resources to conduct successfully, let us say, a legislative campaign in the public interest



Practically, such a campaign might possibly fail Because, if leadership for it were developed from the ranks of the pro-

A 15" x 12" reproduction of this illustration by Harold Anderson is available upon request

COMING: THE GERIATRICIAN

Increasing longevity is prima-facie evidence of medical progress However, as more people grow older, physicians are confronted with an ever-increasing number of clinical problems which arise out of the aging process It is no longer fantastic to assume that geriatrics will someday take its place at the opposite pole from pediatrics as a full-fledged specialty practice

Diseases of the heart, kidney, and blood vessels, pernicious anemia, diabetes mellitus, cancer, and other conditions which strike most frequently after middle age have engaged a large share of the time and thought of Lilly research workers Crystalline digitoxin, liver extract, liver-stomach concentrate, and Insulin are but a few of the important contributions in which Eli Lilly and Company has shared Perfecting existing preparations, as well as searching for answers to unsolved problems, keeps teams of scientists busy at the Lilly Research Laboratories Practical developments are made available to the medical profession wherever ethical pharmaceutical and biological products are sold

Lilly

LILLY SPECIALISTS SERVE THE MEDICAL PROFESSION

portance to the medical profession, since, in the wake of strikes, shutdowns, slowdowns, and unemployment, worry, anxiety, and uncertainty swell the numbers of those who will shortly crowd doctors' offices and increase the patient roster of hospitals already overloaded It is true that unemployment insurance, the departments of public welfare, and the numerous charitable organizations can and do intervene to cushion the acute hardship for a while

But continuing aid of this type seems to us to be unhealthy—a magnificent gesture certainly, but no substitute for a healthy independence Such aid begs the question, does it not? It ignores the cynical leadership which has coerced the working man and woman for the aggrandizement of its own power into walkouts often of an irresponsible nature Such leadership trades upon the immunity granted to labor by the Clayton Act from the ordinary operation of the anti-trust laws Result Loss of independence within the unions, creation of a dependency of the working man to questionable leadership, increase in cost of living for everybody, abuse of public and private charity, creation of public inconvenience affecting union and non-union people alike, aggravation of ordinary and usual illness by unnecessary worry, loss of work and of *the security of independence*

More and more the economic trend is toward the futile goal of higher wages and a putative "security" for union members only, within the larger framework of national social security Viewed dispassionately against the background of the recent national debt (1948) of some $252,292,246,513, or about $1,721 45 per capita, "fixed" charges of $35,000,000,000 a year, and some $5,500,000,000 interest on the national debt, one might well pause to ponder Who is secure from what and for how long?[1]

[1] New York World Telegram Oct 2 1949 p 22

Convalescence Study

In its generally accepted meaning, convalescence is the process of gradual recovery from sickness, it is also the period during which such recovery takes place, and the state of the body during this period Convalescence is not only a medical problem, it has grave financial and other implications

Since the able-bodied must carry the weight of those who are disabled, the problems of convalescence are important to the nation's economy Little has been done in the field of convalescence other than to afford patients an opportunity to rest in a neutral environment with a good normal diet Not content with this simple procedure, a group from St Luke's Hospital, New York City, are now interesting themselves in the basic problems involved during the convalescent period It is their hope to be able eventually to modify the speed of convalescence through specific measures

Technics to be employed include a personalized approach to the problem of each patient, including a careful history of his diet, an evaluation of the social service history and its bearing upon the patient's psychologic attitude toward his or her own physical state, an effort to orient the patient's own thinking about his illness and stimulate in him a positive desire to help himself get well, an attempt to correct any suspected dietary deficiency specifically, using such diet supplements as seem indicated, if the patient is unable or unwilling to eat a sufficient quantity of the proper foods, and an effort to be made to determine the optimum protein intake for various convalescent states An attempt is to be made to determine the best approach to the problem of deficiencies in hemoglobin Other phases are the use of occupational therapy of a specific nature to improve function of specific parts of the body, the effect of the psychologic approach to the patient's particular problem upon the rate of recovery, the study of the effect of high protein feeding upon poor cardiac tone from any cause, and a study of the relationship of the eryth-

fession, such generalship would be seriously deficient in the strategical know-how to conduct it successfully If, on the other hand, the campaign were directed by hired professional nonmedical strategists, these would be considered mercenaries, and a tactical error of the first magnitude would be entailed in some loss of allegiance to such leadership on the part of the individual physician

This creates a serious dilemma Chief among such a society's available resources is the individual physician Can he be developed for leadership in the sense here under discussion? Outside of his practice and in relation to well people, his tactical training and study has not been seriously undertaken, and, with few exceptions, his tactical sense does not exist Possibly more farsighted leadership in the profession should have made the subject of tactics as they relate to well people a matter of curricular study, or at least postgraduate instruction It was inevitable that the expansion of the field of medicine as distinct from private practice would necessitate the development of an art not formerly of great importance in private practice Now it is realized that there is a great need for the comprehensive understanding of what makes well people and groups of well people "tick" So successful has scientific medicine become that the well vastly outnumber the sick and live longer than in the past

Doctors can be trusted to deal scientifically and competently with the sick and their medical care That is their business They are still the sole reliance of this hapless group of people Yet it is the growing horde of the well who dispose of the vast forces of potential disruption What do they think of doctors and the medical profession? The relatively small company of the sick upon whom the doctors pour out their wealth of knowledge and skill are more inclined to be resentful of their illness than pleased by their improvement or recovery Well again, they join the ranks of those who can make or break the future structure of medicine

Tactically, doctors are at a disadvantage in that they lack knowledge of the intentions of the well, they ignore, for the most part, the historical fact of the growing organization of well people into groups whose actions and thought patterns are controllable to an extent, groups whose attitudes can be compelled by rascals as well as by sincere leaders Lacking, themselves, any great amount of cohesiveness by reason of their training as individualists, doctors tend to underestimate the effective striking force of disciplined cohesion in a vast group of well people who resent physicians as the visible symbols of potential pain, frustration, expensive sickness, and disability, all of which, be it noted, the doctors and medical science are laboring mightily to abolish!

It is not too late to commence the tactical training of doctors The A M A, in its Public Relations Bureau, has established a general staff This staff, however, while it can and does map out over-all strategy for the public educational campaign, yet must depend upon lower echelons to make this strategy effective in the field of operations. It is here that the lack of tactical art may prove to be highly obstructive to the accomplishment of the general strategy

It is absurd to jeopardize a campaign by good generalship of poorly trained effectives under field commanders having little tactical sense and less tactical training Let the component units think this over It is not too late, it would seem, to initiate a study of tactics by county societies Some few have done so In this State with a well-organized Public Relations Bureau a beginning was made early this year in the speakers training courses held regionally This training should be followed up and expanded and must include more doctors Only when thousands of physicians all over the nation feel themselves to be a vital, sure, well-informed, well-equipped field force of effectives can a well-led campaign of public education and legislative adequacy be accomplished

The Creeping Paralysis of Dependency, I

As this is written, the principal basic industries of the country—coal, steel, railroads, and many more secondary manufactures—are slowing down This is of im-

turned to other temporarily more popular and novel fields of health endeavor

To meet this situation a Committee on Endemic Goiter was appointed by the American Public Health Association in 1940 under the chairmanship of the late Dr Fred Minor of Flint, Michigan, and included in its membership representatives of the A M A, U S P H S, Food and Drug Administration, Nutrition Board of the National Research Council, the Salt Manufacturers Association, and others This committee, now under the chairmanship of Dr O P Kimball of Cleveland, Ohio, has restudied the evidence as to cause, preventability, and practical measures for prevention which will not demand sustained educational promotion or depend solely on the whim, the assumed self-interest, or the sustained attention of purveyor or purchaser of table salt The committee has agreed that the ideal would be the universal availability of iodized table salt and the disappearance of table salt lacking this essential and trace supplement, except so far as certain religious rituals might require a sodium chloride without iodine added

The difficulties to be overcome are chiefly technical administrative definitions and certain trade practices and customs

All the table salt used by the armed forces in World War II was iodized salt as advised by the National Research Council

Before resorting, if this should prove necessary, to an official definition of table salt which would secure to all purchasers and users the benefits of the small addition of an iodide which would effectively prevent endemic goiter, an understanding has been reached with the manufacturers of table salt to use the channels of trade advertising to promote the exclusive use of iodized salt for table and family purposes

An excellent basic document has recently been published by the United States Public Health Service with the cooperation of the Committee on Endemic Goiter of the A P H A under the authorship of Dr Tom H Sebrell of the National Institutes of Health, which gives in authoritative form the facts and principles of prevention which will be used for educational purposes No better brief statement has been made available under any auspices, and the matter is worthy of sustained interest and active promotion by the medical profession

The minor and major, overt and hidden, temporary and continuing effects on the human body and mind of insufficiency of iodine in the diet can be avoided at no public expense, and at no added cost to the person and family in the United States, if the supply and demand for iodized table salt becomes effective throughout the country to the exclusion of the use of the deficient iodine-free table salt too commonly used at present in house, hospital, hotel, and restaurant dietary practice!

Increases in Our Aged Population A great deal of attention is currently being focused on meeting the educational, health, and other needs of the large crop of war and postwar babies—and rightfully so—but this must not obscure the growing needs of our aged population The resurgence of the birth rate has swelled the ranks of our children, but this must not divert attention from the fact that the number of old people in the population has likewise been increasing rapidly in recent years

> In 1940 there were about 9,000,000 people in the United States at ages sixty-five and over, by 1948 the number had jumped to nearly 11,000,000 Thus, in the short span of eight years our aged population grew by nearly 2,000,000, or by 21 per cent, as compared with an increase of 11 per cent in the population as a whole The proportion of the aged in this period rose from 6 8 to 7 5 per cent of the total population.
>
> The rate of increase since 1940 for people sixty-five and over has varied considerably from state to state and from one region to another In general, however, the New England, the southern, and the midwestern states showed the smallest proportionate rise, while the Middle Atlantic and the western states experienced the largest increase. Maine and Vermont, which have long had a relatively high ratio of old people, recorded smaller increases than any other state—4.2 and 7 8 per cent, respectively At the other extreme are Florida, California, Nevada, and Arizona, with additions to their aged population ranging from 37 to 52 per cent in the eight years under review [1]

That portion of the country which formerly was considered the youngest, in that it was settled latest, now is reaching apparently a staid maturity One associates the settling and early development of the lands of the middle and far West with tales and scenes of violent and, in many in-

rocyte sedimentation rate to the status and activity allowances for rheumatic carditis cases

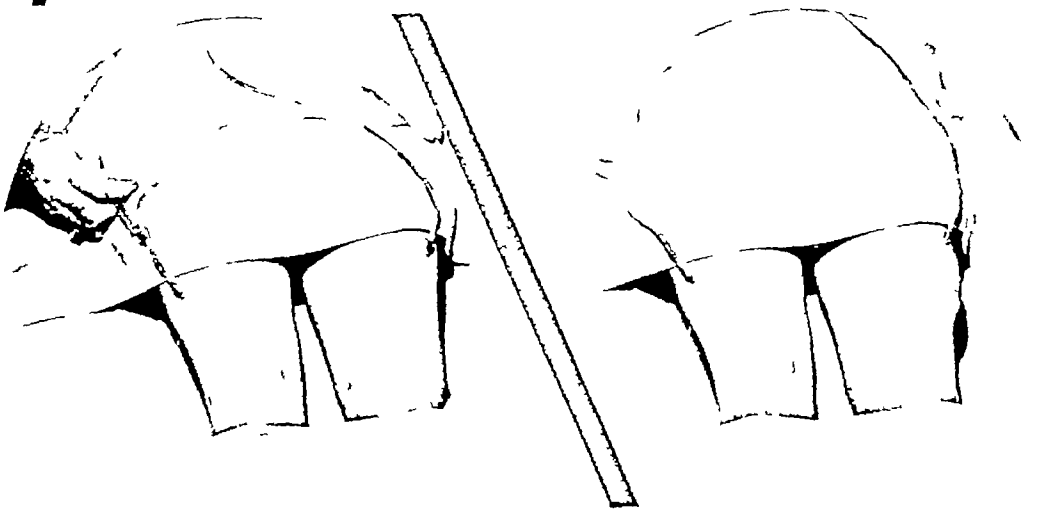
St Luke's Convalescent Hospital in Greenwich, Connecticut, has recently opened a new Nutritional Research Laboratory where basic studies in protein metabolism are now under way An effort will be made to study individual amino acids with regard to their relation to specific pathologic conditions After determining the various changes in amino acid utilization brought about by disease, it is hoped to be able to shorten the period of convalescence by supplying an excess of the specific amino acids, as indicated The effect of various hormones, particularly the steroid group, upon the basic nutritional deficiencies will also be investigated

It is possible that these researches, which it is anticipated will cover a fifteen-year period, may provide much needed short cuts to recovery This is a step in the right direction, in our view, since it opens possible channels for reducing length of stay in hospital, and may provide information whereby incapacitated workers may return more quickly to their jobs

We feel that the slowly changing mean age of our population makes it imperative to know all we can about the needs of those above fifty years of age Theoretically, it will become essential in the not too distant future to keep many more of the population productive past the age of fifty Any information which can be obtained with regard to the essential factors of nutrition in the older age group can be used to great advantage in maintaining a productive citizenry

Current Editorial Comment

Permanent Automatic Prevention of Endemic Goiter It is almost thirty years since the first systematic attempts were made in the United States to reduce and control the incidence of endemic goiter, benign nontoxic hyperthyroidism, among school children, first in Akron and Cleveland, Ohio, and later on a more extended scale in Detroit and smaller cities of Michigan and in some of the other states of the Great Lake's goiter belt and in the Northwest These efforts were strikingly successful largely under the leadership and the technical direction of Drs David Marine and O P Kimball of Cleveland and with the widespread support of physicians in private practice and in public health positions



A solution of iodide of soda was provided for use medicinally during a week or ten days twice a year to all children attending the public and parochial schools in Cleveland In the campaign in Detroit and other Michigan communities table salt containing a small amount of iodide was provided by the salt manufacturers, with no increase in cost to the retail purchaser It was common to find over a period of five to ten years a reduction in incidence of appreciable hyperthyroidism among the children of families who made a practice of using iodized salt, from nearly 30 per cent to less than 5 per cent

The medical profession became convinced that this use of iodized salt had no unfavorable toxic, irritative, metabolic, or dermatologic results Toxic hyperthyroidism also showed substantial reduction among communities availing themselves generally of the dietary preventive resource of iodized salt

Experience of the trade showed that substantial amounts of iodide were lost in processes of packaging, transporting, storing, exposure to varying warm temperatures, and from other factors This was corrected by the use of "stabilizers" to hold the iodide in the salt container and by improving the carton package

The general picture was favorable and a slow but encouraging extension occurred in the percentage of iodized table salt sold at retail, but rechecking of the goiter incidence by the committee of pediatrists and their surgical and internist associates in Michigan revealed a gradual increase of goiter among school children and a lack of established purchasing habits among parents of buying only iodized table salt As the wave of educational and professional interest waned, public indifference followed, and teachers, parents, and physicians

Speed...Comfort...Safety...

Start of hypodermoclysis
Alidase injected in right leg
No Alidase used in left leg

Completion of hypodermoclysis. Right leg: comfort, safety, rapid absorption
Left leg: swelling, pain, slow absorption

ALIDASE* Searle (highly purified hyaluronidase) injected through the hypodermoclysis tubing makes it possible to administer subcutaneous fluids with the speed, comfort and safety of the intravenous route

Clinical studies have demonstrated that Alidase markedly increases the rate of absorption of saline, plasma, glucose, Hartmann's or Ringer's solution The absorption of penicillin, streptomycin, procaine and adrenalin is also facilitated

The swelling, induration and discomfort which ordinarily accompany hypodermoclysis are negligible when Alidase is employed

USUAL DOSE: One ampul per 500 to 1,000 cc. of hypodermoclysis fluid

ADMINISTRATION It may be (a) injected through the wall of the rubber tube near the hypodermoclysis needle or (b) dissolved directly in the solution (when the amount of fluid to be injected is small)

stances, early death It is hard to envision that area as now populated by the aged descendants of those violent and hardy pioneers

Of special interest are the population changes which have been taking place on the West Coast The old age population in the three Pacific Coast states as a group increased 36 5 per cent, outranking by a considerable margin all the other regions in this respect, for California alone the rise was as much as 41 4 per cent Despite the very sizable additions of old people to the Pacific states, the proportion of the aged in relation to the total population actually decreased from 8 1 to 7 7 per cent between 1940 and 1948 This paradox is explained by the phenomenal influx into this area of young adults and their children

Every state, without exception, has added a considerable number of people sixty-five and over to its population since 1940 In some areas the increase has been remarkably large New York State, for example, has added nearly a quarter of a million older people in this short period, California more than 230,000, Pennsylvania and Illinois about 130,000 each, and Ohio a little more than 100,000 The magnitude of the problem is, of course, better gauged by the total number of aged in the various states Thirteen states each have more than a quarter of a million old people, and of these five have more than one half million, in New York State the aged number about 1,200,000

Even before the war the medical, recreational, housing, and other facilities needed by the aged were grossly inadequate With the marked increase in the old age population, the situation has become more critical And, as has been pointed out in the *Bulletin* so often, the older people will continue to increase both in absolute numbers and as a proportion of the total population It would be the better part of wisdom to make provision for their growing needs Fortunately, official and voluntary agencies in many communities throughout the country are already studying the problem seriously and taking steps towards its solution.

Silver threads among the gold create a costly and vexing problem in custodial and other care for Father William who, when young, if memory serves us, says he—

Took to the law
And argued each case with my wife
And the muscular strength which it
gave to my jaw
Has lasted the rest of my life

OFFICE MANAGEMENT OF VENEREAL DISEASES

"The time has now arrived when the diagnosis and treatment of venereal diseases should properly revert to the office of the private physician" are the words prominently displayed on the cover of a valuable and useful booklet recently issued by the Bureau of Social Hygiene of the New York City Department of Health, in cooperation with the New York State Department of Health and the United States Public Health Service This booklet outlines for the physician the management of venereal disease patients and is up-to-date on the new methods of treatment, including penicillin and other antibiotic agents, although the final word on these remedies cannot be written at this time

The publication is well worthy of the attention of the practitioner and may be obtained from the Department of Health, 125 Worth Street, New York 13, New York.

METHODS OF TUBERCULOSIS CASE-FINDING IN THE COMMUNITY

MASS CHEST X-RAY SURVEY

A Summary of Follow-Up Findings in 200,000 Patients Examined in Erie County, New York

MILLER H SCHUCK, M D , and WENDELL R AMES, M D , Buffalo, New York

(*From the Buffalo and Erie County Tuberculosis and Health Association and the Erie County Health Department*)

THE mortality from tuberculosis has been higher in Buffalo and Erie County than in any other portion of upstate New York There had been a decrease, it is true, during the period from 1900 to 1948, but the rate for Buffalo in 1948 was 44 per 100,000 in contrast to 35 5 for New York State as a whole

The Buffalo and Erie County Tuberculosis Association was fully cognizant of the special local problem and, after consultation with the Department of Health, decided to purchase and staff a mobile photoroentgen unit which could be utilized in all parts of the city and county The unit was to be used for a full-time, continuous survey instead of an intensive spot survey over a short period of time Our purpose is to present, in brief, the organization of the survey program and a summary of the findings from the 200,000 survey films which were taken during the period from March 4, 1946, through January 19, 1949

The estimated population of Buffalo is 611,932 and that of the entire county, including Buffalo, is 876,710 This is a highly industrialized area, and there is a thorough mixture of nationalities and races There are approximately 30,000 Negroes in Erie County as a whole, and about 40 per cent of the population is of Polish and Italian descent There are smaller groups of German, Irish, and Slavic nationalities During the war years there was a very considerable migration of Negroes from the Southern agricultural areas, and many diagnosed patients either did not attempt treatment or left sanatoria against advice However, all of these factors were known to exist in other areas with a lower mortality rate from tuberculosis, and it was presumed that the high rate locally might be from the combination of undiagnosed cases and from lack of isolation of known patients It was thought that a mass survey program would help to eliminate the former factor

During early 1946, a 70-mm photoroentgen unit was delivered, this being of the tractor-trailer type with a self-contained power generator Personnel on the trailer included two technicians and a secretary A full-time director was employed for the highly important task of supervising operation of the unit, interviewing employers and civic groups, and arranging schedules One physician was made responsible for the reading of all films, conducting the two check-up clinics, and forwarding reports of findings to patients and physicians A full-time secretary and statistician with special training in other survey programs has been responsible for the transfer of information to the index cards and compilation of findings

The minimum age was set at fifteen years, but a considerable number of younger persons have been examined, usually because they had family contact Some younger individuals were also included in the high school surveys, since the junior and senior classes were checked, regardless of age

All of the survey films demonstrating either

per cent were in the group fifty-five through sixty-four years, and only 2 per cent of the total were over sixty-five years of age

In Table 2 the attendance has been shown according to race as well as age and sex The preponderance of young adults in the age group fifteen through thirty-four years was noted again, in fact, the percentage of attendance in the various age groups was essentially the same for the white and nonwhite groups

Findings on Miniature Film

A total of 337 people (1 7 per 1,000) were classified as "definite tuberculosis," admittedly a low figure, but it was our purpose to be conservative in presumptive as well as final diagnoses There was a strikingly uniform progress on in the rate per 1,000 in each older age group, this being true of both white and nonwhite groups In the age group zero to fourteen the rate per 1,000 was only 0 129 for whites, but in the twenty-five to thirty-four group it had jumped to 1 44, and in the age group sixty-five and over it was 6 72 (Table 3)

The major portion of films showing abnormal findings were classified as "suspicious tuberculosis," and these totaled 2,075 or 10 5 per 1,000 Here again, the number of films so classified showed a progressive increase with each of the older age groups In the fifteen to twenty-four age group, 4 56 per 1,000 were classified under this heading, but the number had increased to 41 1 per 1,000 in the age group of sixty-five and over There was no gross difference in the white and nonwhite groups

In the white group a breakdown of the "definite" and "suspicious tuberculosis" cases according to sex showed that there were approximately equal numbers of males and females in the age group from fifteen through thirty-four years, but in the succeeding age groups there was a preponderance of males In the nonwhite group, this difference between the sexes was not apparent, possibly due to the small number examined

In summary, 12.2 per 1,000 were classified as either "definite" or "suspicious" tuberculosis on the basis of findings in the small films, 277, or 1 4 per 1,000, were thought to have cardiac abnormalities and 779 (4 per 1,000) were found to have nontuberculous pulmonary changes

Results of Follow-Up Examinations

In Table 4 we have shown the final diagnoses after additional study and re-examination with conventional 14- by 17-inch films In the group of 337 originally classified as "definite tuberculosis" there were only 209 who were retained in that category, while 88 were classified as "apparently cured" and seven were continued as

questionable or definitely abnormal findings were cut from the roll by the interpreter and a form letter sent to the individual concerned requesting that he return for a large check-up film When he reported, a detailed history was obtained, physical examination of the chest was carried out, and the necessary 14- by 17-inch films were taken When indicated, tuberculin tests were done, fluoroscopic check-up was made, and directions were given regarding the collection of adequate sputum samples A brief report was then forwarded to the patient and a more detailed report to the family physician In some cases, of course, it was necessary to make repeated examinations for accurate evaluation, but every effort was made to get the patient back and the first report to the doctor in a period of not more than ten days It was thought that a longer delay created poorer cooperation on the part of the patients and caused them to underestimate the importance of the findings

Patients who did not respond to the first request to return received a second letter, and, in case there was still no response, the survey film as then turned over to the Health Department and a nurse made a personal visit to encourage cooperation Patients who appeared to have cardiac pathology were notified through the Visiting Nurses Association and advised to see their family physician Some patients were requested to return to our own check-up clinic when the underlying condition was not obvious and there was a differential diagnosis such as that involving aortic aneurysm and mediastinal mass

Distribution According to Age, Race, and Sex

Although 200,000 films were taken, 2,625 were excluded since they were unsatisfactory or were taken on patients outside the county and were not rechecked here, leaving 197,375 films to be included in this study

In Table 1 we have shown the attendance according to age and sex Somewhat to our surprise, there was practically equal representation of the sexes in all age groups There was, on the other hand, much better attendance in the younger age groups Sixty and two-tenths per cent of all the people examined were in the age group fifteen through thirty-four, while only 5 7

per cent were in the group fifty-five through sixty-four years, and only 2 per cent of the total were over sixty-five years of age.

In Table 2 the attendance has been shown according to race as well as age and sex. The preponderance of young adults in the age group fifteen through thirty-four years was noted again, in fact, the percentage of attendance in the various age groups was essentially the same for the white and nonwhite groups.

Findings on Miniature Film

A total of 337 people (1.7 per 1,000) were classified as "definite tuberculosis," admittedly a low figure, but it was our purpose to be conservative in presumptive as well as final diagnoses. There was a strikingly uniform progression in the rate per 1,000 in each older age group, this being true of both white and nonwhite groups. In the age group zero to fourteen the rate per 1,000 was only 0.129 for whites, but in the twenty-five to thirty-four group it had jumped to 1.44, and in the age group sixty-five and over it was 6.72 (Table 3).

The major portion of films showing abnormal findings were classified as "suspicious tuberculosis," and these totaled 2,075 or 10.5 per 1,000. Here again, the number of films so classified showed a progressive increase with each of the older age groups. In the fifteen to twenty-four age group, 4.56 per 1,000 were classified under this heading, but the number had increased to 41.1 per 1,000 in the age group of sixty-five and over. There was no gross difference in the white and nonwhite groups.

In the white group a breakdown of the "definite" and "suspicious tuberculosis" cases according to sex showed that there were approximately equal numbers of males and females in the age group from fifteen through thirty-four years, but in the succeeding age groups there was a preponderance of males. In the nonwhite group, this difference between the sexes was not apparent, possibly due to the small number examined.

In summary, 12.2 per 1,000 were classified as either "definite" or "suspicious" tuberculosis on the basis of findings in the small films, 277, or 1.4 per 1,000, were thought to have cardiac abnormalities and 779 (4 per 1,000) were found to have nontuberculous pulmonary changes.

Results of Follow-Up Examinations

In Table 4 we have shown the final diagnoses after additional study and re-examination with conventional 14- by 17-inch films. In the group of 337 originally classified as "definite tuberculosis" there were only 209 who were retained in that category, while 88 were classified as "apparently cured" and seven were continued as

* In addition 211 cardiacs found on the Mobile Unit Survey films were referred directly to the private physician.
† In this group 101 possible neoplasm cases were diagnosed. Of the 101 there are 21 cases in which definite diagnosis of neoplasm has already been made

"suspicious tuberculosis." In the group of 2,075 originally classified as "suspicious tuberculosis," only 416 were given a diagnosis of "definite tuberculosis," 459 were classified as "apparently cured," and 162 were continued as "suspicious tuberculosis." Five cases of definite tuberculosis were screened from other groups, and there were, therefore, 632 individuals (3.2 per 1,000) who were found to have clinically significant and reportable disease, and 597 (3 per 1,000) cases of apparently cured, nonreportable disease.

Four hundred ninety-one, or 78 per cent, of the patients were found to have minimal disease, 202 were classified as active, and 289 inactive. There were 127, or 20 per cent, moderately advanced cases, 86 active, and 41 inactive. Only 14, or 2 per cent, advanced cases were discovered, but 13 of these were active. The preponderance of minimal disease, 78 per cent of the total, is in striking contrast to the older figures for extent of disease at the time of admission for sanatorium care. Only 19 per cent of all persons examined fell into the age group of forty-five and over, but this group contained 41 per cent of the patients found to have reportable disease.

Careful checking with the central tuberculosis register revealed that only 61, or 10 per cent, of the reportable cases had been previously known. This finding was in direct contrast to the opinion of many people at the time the survey was instituted (Table 5).

Comment

The Mobile Unit Survey has been different from most other programs in that (1) careful follow-up of findings on miniature film was made by the same staff, (2) the survey was county-wide, but one hundred per cent coverage in individual areas was not attempted, (3) the survey has been continuous since it was first started during March, 1946. The yield of 3.2 clinically significant cases per 1,000 is much lower than the 13 per 1,000 reported by Christie from the survey made during 1948 in Washington, D. C., but the fact that 90 per cent were newly discovered patients and that 78 per cent of these were in the minimal stage made the screening process profitable.[1] If the group of 597 apparently cured, nonreportable cases are included, the total yield is 6.2 per 1,000. We feel that the yield may have been appreciably diminished by including a higher percentage of the age group fifteen to twenty-four, especially through surveying the junior and senior classes in the various high schools. We also realize that there has been duplication, since in several instances industrial groups were surveyed twice during the two-year program. A special study has been conducted at the University of Buffalo.

TABLE 5.—Clinically Significant Tuberculosis on Follow-Up Examinations According to Age and Sex

Age Groups	P1 Male	P1 Female	P2 Male	P2 Female	P3 Male	P3 Female	Total Male	Total Female

Total	255	236	79	48	10	4	344	288

School of Medicine which includes a chest x-ray for each student three times each school year, and this group also has been included in the total reported

The high yield of significant cases from the older age groups has been stressed by Medlar and Boyd, and the fact that 41 per cent of our reportable cases came from the age group forty-five and over coincides with this opinion [2,3]

Up-to-date figures are not available, but the 1940 census showed that 29 per cent of the population in Erie County was made up of people forty-five years of age or older Eighteen and eight-tenths per cent of this survey group were forty-five years of age or older, and, therefore, we appear to be neglecting the most important segment of the population

Summary

1 Survey films (197,375) during the period from March 4, 1946, through January 19, 1949, led to eventual diagnosis of 632 reportable cases of tuberculosis (3.2 per 1,000) and 597 cases of nonreportable, apparently cured disease, 78 per cent were minimal in extent, 28 per cent moderately advanced, and only 2 per cent advanced

2 Only 18 8 per cent of all those examined fell into the age group of forty-five and over, yet 41 per cent of the reportable cases were in this age group

3 From miniature films alone, 1 4 per 1,000 were thought to have cardiac abnormalities, and 4 per 1,000 were found to have nontuberculous pulmonary pathology

4 Only 61, or 10 per cent, of the reportable cases had been previously known to the Health Department

5 The incidence of reportable pulmonary tuberculosis was no higher in the nonwhite than in the white group

We are indebted to Mrs. Dorothea Voltermann statistician and secretary-technician, Buffalo and Erie County Tuberculosis Association for tabulation of findings and her wholehearted interest in this survey

NIAGARA FALLS MASS CHEST X-RAY SURVEY

Community Organization

JERAULD A CAMPBELL, M D ,* Niagara Falls, New York, WILLIAM SIEGAL, M D , and HERMAN E WIRTH, M D , Albany, New York

(From the Niagara Falls City Health Department and the New York State Department of Health)

THE first total population, chest x-ray survey using multiple mobile photoroentgen units in New York State was conducted in the City of Niagara Falls from October 18, 1948, to December 10, 1948 The object of the survey was to x-ray the chests of 80 per cent of the population age fifteen and over and, in so doing, to uncover cases of tuberculosis in their early stages

Early diagnosis of tuberculosis is still a problem in Niagara Falls, as indicated by the fact that 75 per cent of the cases reported during the first seven months of 1948 were either moderately or far advanced Thus, our existing case-finding facilities had been a failure when judged by their ability to find tuberculosis early These facilities consisted of a follow-up and examination of all known cases and contacts, maintenance of a case and contact register for the past ten years, two chest x-ray clinics per week, one for routine films and unreferred individuals on 70 mm film and the other one on standard 14- by 17-inch film for physicians' referrals and for follow-up of those showing indications of pathology on the small films In addition, both local hospitals routinely x-ray the chest of a patient on each admission However, this last detail of the program was not inaugurated until May, 1948 One local industry employing about 2,000 persons routinely x-rays all its employes once each year

* By invitation.

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Public Health, Hygiene and Sanitation May 4 1949

Preliminary Planning

During the early part of 1948, plans for a chest x-ray survey were promoted by the Tuberculosis and Health Association of Niagara County and by the Niagara Falls Junior Chamber of Commerce This was to have been a limited survey using a single transportable unit for a period of one month However, before this plan could be put into execution, the State Department of

Health made known its intention to employ sufficient equipment and personnel for total population surveys within a very short time In view of the possibility of such a comprehensive survey, the plans for a limited survey were abandoned However, considerable interest had developed in mass surveys as a result of this abortive effort, and, when equipment and personnel were available, the State Department of Health offered them to the City Health Department for a total population survey

At a preliminary conference between representatives of the State Department of Health, the City Health Department, the Niagara Sanatorium, and the Tuberculosis and Health Association, a tentative plan was developed for the survey Under this plan, all medical and technical equipment, as well as adequate personnel for taking and reading of 70 mm films, were to be supplied by the State Department of Health Office space and equipment, communications, follow-up clinic facilities, and publicity and promotional expenses, as well as the stenographic and clerical personnel, were to be supplied locally Interpretation of follow-up films and reporting of findings were to be made by the superintendent of Niagara Sanatorium It was agreed that this tentative plan would be presented to various groups in the city whose cooperation would be necessary and that a survey should be conducted at this time only if real interest in the project was forthcoming Approval by the local medical profession was a specified prerequisite Also, since Niagara Falls is a heavily industrialized city with almost one third of the entire population employed in industry, it was felt that the unqualified approval of both management and organized labor was absolutely imperative

The tentative plan was presented to the Niagara Falls Academy of Medicine which voted unanimously for its endorsement A special meeting of the Industrial Health Committee of the Tuberculosis and Health Association was called Representatives from several of the major industries and from the three major unions in the city, the C I O, A.F of L, and U.M W, attended Since x-raying the workers on the job was part of the plan, considerable concern was evinced by industry as to how much interruption in production schedules might be involved and the monetary loss resulting from such interruption A detailed explanation of technics to be used and the speed with which the actual x-raying could be done served to reassure this group The labor leaders present were frankly skeptical as to the confidential nature of reporting, fearing that x-ray findings would be available to employers Representatives of the State and local health departments present guaranteed that reports would be available only to the individual and his own physician. With this assurance, the survey was endorsed by each of the three major unions

With the cooperation of industry and labor assured, the next step was to enlist the cooperation of the general public A general meeting was called at the City Hall with invitations extended to representatives of a wide variety of community organizations, service clubs, veterans' organizations, and religious and fraternal leaders. From the groups which attended this meeting, a general planning committee was selected for over-all supervision of the survey One of the city's leading industrial executives accepted the chairmanship of this committee and selected a small executive committee for detailed planning and administration.

Organization

The necessity for a full-time program director was recognized, but funds were not available for employing such a person Moreover, it was unlikely that anyone who had adequate knowledge and experience in both tuberculosis and survey methods would be available This problem was solved by requesting the Tuberculosis and Health Association to grant its executive secretary a ten weeks leave of absence from his regular duties so that he might serve as program director This request was granted

During the ensuing two weeks, conferences were held with representatives from the Divisions of Tuberculosis Control and Public Health Education of the State Department of Health, and the organizational plan necessary to meet our needs was developed Subcommittees were decided on as follows (1) Unit Location Planning, (2) Zone and Area Organizing, (3) Publicity and Public Information, (4) Professional Services, (5) Industrial, (6) Schools, and (7) Finance

The chairmen of these subcommittees were chosen by the executive committee The membership was developed by consultation between the general chairman and the individual subcommittee chairmen

Subcommittee Activities

Unit Location Committee—This committee functioned under the chairmanship of the city editor of the local newspaper Since a satisfactory source of power was necessary at each location, a representative from the local utilities company was a valuable member The committee first divided the city into nine working units, designated as zones This division was determined by a consideration of trading centers, natural barriers, main thoroughfares, and population density Each of these zones was then subdivided into smaller units, designated as

areas, each of which was to have a unit location Schools, firehalls, churches, and business establishments seemed most suitable for transportable units and street locations for the mobile bus units When the locations had been established, permission for the use of the premises obtained, and power sources checked, a tentative schedule for the eight weeks of the survey was set up

Zone and Area Organizing Committee—This committee began to function as soon as the city had been mapped into zones and areas and the unit locations had been established The chief objective of this committee was to see that every home in the city was visited by an informed neighborhood canvasser, who would explain the survey and invite families to take advantage of the opportunity when the unit came to their neighborhoods The committee was guided and assisted in this work by one full-time and one part-time health educator assigned to the project by the State Department of Health The committee selected leaders for each of the nine zones, and, in conference with these zone leaders, area leaders were selected Each area leader then recruited a corps of block workers, usually at least two for each block A schedule of orientation meetings for block workers was then arranged and coordinated with the unit location schedule so that the meeting preceded the arrival of the unit in the area by about one week These meetings, presided over by a health educator, served to acquaint the block workers thoroughly with the benefits to be derived from the survey so that they might better be able to overcome indifference or opposition encountered during their canvassing Publicity materials to be left at homes during the canvass were distributed, including a pamphlet containing questions most frequently asked and the proper answers to them

The canvasser's visit was reinforced by a flyer delivered to each home one or two days before the x-ray unit was to move in This flyer gave the exact location and hours of operation of the unit as well as alternate locations in adjacent areas Boy Scouts, Girl Scouts, and the Junior Red Cross delivered the flyers under the direction of the committee chairmen

This house-to-house canvass was probably the most effective single activity contributing to the ultimate success of the project In all, 500 block workers visited more than 22,000 homes

Publicity and Public Information—The chairman of this committee acted as director of publicity Since the funds available for this phase of the project were rather inadequate, as much use as possible was made of free and donated forms of publicity During the planning stages of the survey most of the publicity was in the form of newspaper accounts of the progress in various phases of the preparations To eliminate the possibility of a lack of interest resulting from a protracted campaign, intensive publicity was purposely withheld until about one week before the actual beginning of operations The director's plan was to avoid using all types of publicity at the beginning of the survey so that interest could be maintained throughout the entire eight weeks by the periodic introduction of publicity devices and promotions

The city editor of the *Niagara Falls Gazette* assigned one reporter for the duration to write up the survey developments All stories were cleared through the publicity director and checked by the health officer for scientific accuracy

The two local radio stations were supplied with a series of spot announcements, which were plugged daily throughout the survey, and special programs were given in Italian and Polish

Special publicity devices included posters, movie trailers, leaflets, inserts in department store monthly billings, painted sidewalk signs, sound trucks, and milk bottle collars At the midpoint of the survey a special four-page pictorial spread was featured in the rotogravure section of the Buffalo Sunday newspaper

Professional Service Committee—This committee, composed of members selected from the local medical and dental professions, checked all procedures and publicity materials to insure their acceptability from the standpoint of ethics and scientific accuracy This committee also prepared and sent out a letter to all physicians advising them of the routine to be followed and the manner of reporting to private physicians

Industrial Committee—This committee assumed full responsibility for x-raying in industry The city was divided into five industrial zones with a chairman for each, usually the personnel manager of one of the larger plants Two bus units were assigned to industry for its exclusive use Most Niagara Falls industry is electrochemical and electrometallurgical, operating continuous processes Thus, scheduling had to provide for day, night, and "swing" shifts Blank cards were supplied to each industry and made out in advance from their own payroll and personnel records With cards thus prepared in advance men could be x-rayed in small groups with a negligible loss of time

The industrial committee also handled publicity within the plants Notices were posted by both management and union officials

Schools Committee—This committee was active in arranging unit locations in the schools in directing the x-raying of students age fifteen and over as well as teachers, custodians, engineers, and lunch room personnel This committee conducted an intensive educational campaign designed chiefly to reach the parents through the

children. The importance of tuberculosis control and the value of the survey were stressed in the health and biology classes in the secondary schools In the elementary schools the teachers taught the children a few simple facts to take home to their parents along with leaflets and schedule flyers

Finance Committee—This committee was responsible for allocation of funds, approving all expenditures and limiting them to the budget A total of $6,000 was available, this amount appropriated by the City of Niagara Falls

Survey Center

Headquarters were necessary to house and coordinate the various activities of the survey other than the actual x-raying Fortunately, ample space was available in the City Chest Clinic, and this was converted and expanded to serve as a center of operations Included in this center were the administrative headquarters of the program director, the tuberculosis consultant, the supervising technician, the health educator, and the office manager Facilities were provided for interpretation of 70 mm film, for interviewing and history taking by the public health nurses, and for developing both 70 mm. and 14- by 17-inch film

Management of administrative details connected with the survey was the responsibility of the office manager The office manager served in this capacity in addition to her regular duties in the City Health Department Her responsibilities included equipping and arranging the survey center to accommodate the operating staff, the employment and supervision of stenographic and clerical personnel, the direction of processing of records and medical reports with the assistance of the records consultant, and the maintenance of an accounting system for local funds

Budget limitations did not permit the employment of all the clerical personnel needed After the needs of the survey center were met, only four clerks remained to serve with the seven units operating Soon it became evident that, since one unit operating at capacity required the services of three clerks, a considerable number of volunteer clerical workers would be required Volunteers were secured from a panel of such workers maintained by the local Red Cross and from the local secretarial association. Assignments were made daily by the health educator from this roster

Results and Comment

The only real gauge of the effectiveness of the organization of the community for such an effort as this is the results obtained. Since more than 75 per cent of the total eligible population of city was x-rayed, the community organizat might be deemed adequate However, analy of the 25 per cent not x-rayed, especially as to t age and sex groups into which they fall, will useful information for guidance in future surve

The most serious shortcoming in the comm nity organization for this survey was the lack experience in total population surveys by ever one concerned This was, to a great degre counterbalanced by the enthusiasm and effo demonstrated by the hundreds of lay worke involved We were fortunate in our selectio of a general chairman whose judgment in th choice of subordinates was excellent

As the survey progressed, certain deficiencie were made manifest The program director of such a project should be experienced not only in survey methods but also in medical, technical, organizational, and administrative aspects Such an individual will rarely be resident in the community surveyed It was felt in Niagara Falls that the program director should be supplied on the State level of either the official or voluntary agency

There was a certain amount of inertia in the earlier stages of planning, and the necessity for maintaining a strict time schedule was not fully realized This was particularly true in the organization of the house-to-house canvass With seven units operating, the survey moved through the city at a fairly rapid pace so that the area-organizing groups were sometimes hard pressed to keep ahead of the units The entire organization of each zone should have been completed at a considerably earlier date Had this been done, some of the last minute emergency organization could have been avoided

The budget for carrying out local responsibilities was inadequate, and this situation was further complicated by the lack of any fluid funds Since the only finances available were those supplied by the city, all expenditures had to go through the usual routine including competitive bids and council approval of major items This often caused serious delays in a schedule which was already rather crowded In another survey an effort might be made to secure fluid funds through contributions from voluntary agencies so that something more than minimum essentials might be available

The Niagara Falls survey not only contributed to the improvement in the local tuberculosis control program, but it also served as a suitable testing ground for initiating the State-wide program of total population surveys in major cities It is hoped that the experiences gained in this survey will be of value in the planning and execution of future similar efforts

NIAGARA FALLS MASS CHEST X-RAY SURVEY

Procedures and Results

WILLIAM SIEGAL, M D , HERMAN E WIRTH, M D , Albany, New York, and
JERAULD A CAMPBELL, M D ,* Niagara Falls, New York

(From the New York State Department of Health and the Niagara Falls City Health Department)

CHEST x-ray surveys of total populations of communities in relatively short periods of time are now recognized as an integral, necessary function of the case-finding aspect of any well-organized tuberculosis control program. Such surveys result in the finding of many unknown, mostly asymptomatic, early cases of tuberculosis which the routine examination of contacts and of persons with symptoms would not discover Mass surveys, therefore, have an importance equal to that of established clinics in the discovery of new cases

The longer tuberculous individuals remain undiscovered, the greater the number of secondary cases which may result from them, so that the shorter the period of time taken to find all the cases in the community, the fewer will be the secondary cases which will develop The need for completing mass community surveys as rapidly as possible, therefore, is obvious

This paper is a report of the appraisal of the problem and facilities, the objectives, the procedures employed, and the immediate results in the total population chest x-ray survey of the City of Niagara Falls, New York, conducted in the fall of 1948 The distinguishing features of this survey which warrant this presentation are as follows

1 This was the first total population survey of a city of over 50,000 population in New York State.

2 Tentative diagnoses of definite or suspected tuberculosis and an estimate of clinical status were made on the basis of the interpretations of the survey films

3 Persons whose survey films were considered to show definite or suspected tuberculosis were x-rayed on standard 14- by 17-inch films at the survey headquarters as soon as possible, usually within two weeks after the small film survey x-ray

4. Reports of negative films or notices to consult their physicians or appear for re-examination at the survey headquarters were received, by all those x-rayed, no later than two weeks after the initial x-ray

* By invitation.

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Public Health, Hygiene and Sanitation May 4 1949

Appraisal of Problem and Facilities

The estimated population of Niagara Falls is 89,000 About 66,000 are fifteen years of age or over About three quarters are native-born, most of the foreign-born are Polish or Italian Aside from its prominence as a tourist center, the city is highly industrialized, about half of the working population being engaged in manufacturing plants, the most important of which are in the electrochemical, electrometallurgical, and the printing and publishing fields

With a tuberculosis death rate for 1947 of 22 4 per 100,000 population and an average for the three years 1945 through 1947 of 25 9, Niagara Falls was well below the average for cities of 25,000 population or over in the State Since 1926, when tuberculosis deaths began to be allocated by place of residence, there has been a 63 5 per cent decline in the death rate

Niagara Falls also benefits from the services of a health department in charge of a full-time health officer and facilities for follow-up and for hospitalization of tuberculosis patients in the 200-bed Niagara Sanatorium, a county tuberculosis hospital In view of these favorable circumstances, a total population chest x-ray survey seemed definitely desirable and necessary to supplement existing case-finding procedures At the same time it would afford an opportunity for that city to be the first of the class of cities of 50,000 population or over in New York State to carry such a project to a successful conclusion.

As a result of this appraisal of the local problem and review of facilities, the health officer organized a survey committee, presented the facts to it, and recommended that a total population survey be undertaken. It was determined that such a survey was feasible, plans and procedures for the survey were prepared and an application submitted to the State Health Department for x-ray survey service This application was approved, and the duration and dates for the survey scheduled In approving this application, there were made available to the Niagara Falls Health Department the following facilities in terms of equipment, supplies, personnel, and services

1 Seven photofluorographic machines, four

4 A records analyst, responsible for the machine processing and running tabulation of records, for the smooth flow of these records, and for distribution of reports

5 A supervising technician to assist with daily scheduling and location of x-ray machines, especially with regard to electrical power requirements

6 Two physicians for interpretation of films and to assist, advise, and provide consultation with regard to any aspect of the survey

7 One full-time and one part-time public health educator to provide consultation and advice and to assist with the community organization for the survey

8 All record, report, and tabulation forms

Objectives

The object of this survey was to x-ray as many of the estimated 66,000 adults (those fifteen years of age or older) in Niagara Falls as could be reached, the ideal being 100 per cent, of course Practically, in any large community survey, if 80 per cent of the adults can be reached for x-ray, it may be considered a successful, satisfactory survey Eighty per cent of the adult population of Niagara Falls is 52,800

It should be realized, of course, that the x-raying of these people and the discovery of new cases of tuberculosis among them are only the immediate objectives These, in turn, must lead to the eventual objectives, namely, the control through supervision or hospitalization of the newly discovered cases, as indicated by follow-up study, and thereby the interruption of the cycle of infection and development of new cases

Procedures

Eight weeks were allowed for the entire survey, with a goal of 55,000 x-rays to be taken in that period, a goal which fell short of being realized by a scant 3,000 The survey was conducted from October 18 through December 14, 1948

Every person x-rayed received (1) a report to that effect if his x-ray was negative, or (2) a letter to consult his physician if the x-ray indicated nontuberculous intrathoracic pathology, or (3) a letter to return to the survey headquarters for a second x-ray on 14- by 17-inch film, at which time a history was taken and arrangement made for sputum examination if the survey x-ray film showed definite or suspected tuberculosis It was realized that to retain the interest of the community and thus contribute to the success of the survey, the time between the taking of the x-ray and the notification of the individual of the result of the x-ray should be as short as possible. Actually, only rarely did it take longer than ten days for the person x-rayed to receive his report or notification The report card part of the record was mailed to each individual whose x-ray was negative Where the films showed evidence of intrathoracic pathology, the individuals concerned were notified by form letter

In order to utilize the public health nursing service to the best advantage and to provide proper supervision of tuberculosis cases as soon as possible, the physicians who interpreted films made provisional or tentative diagnoses of definite or suspected tuberculosis on the basis of the survey films In addition, they made an estimate of the clinical status of the disease on the same basis, that is, if a tentative diagnosis of tuberculosis was made, whether the disease was probably active or probably inactive Where the disease was estimated to be probably active, the extent of involvement or the stage of the disease was also noted as minimal, moderately advanced, or far advanced

Individuals whose films showed significant abnormalities were notified by letter, the contents of which differed according to whether the diagnosis was definite or suspected tuberculosis or some nontuberculous condition If a nontuberculous condition was diagnosed, the individual concerned was notified to visit his physician to whom the report containing the interpretation, diagnosis, and recommendations had been sent

If definite or suspected tuberculosis was diagnosed, the individual concerned was notified to report on a specified date to the survey head-

quarters where facilities were available for a confirming x-ray, with upper clothing removed, on 14- by 17-inch celluloid film At the same time, a short medical and social history was taken, the name checked for previous report as a case of tuberculosis, and a sputum specimen container given to the patient with instructions as to how to collect the specimen and where to deliver it The report which was sent to the patient's physician was the *interpretation of this first* follow-up 14- by 17-inch film and made possible in these cases a more detailed, accurate description and diagnosis For persons who did not return for their first 14- by 17-inch follow-up film, the survey film interpretation was still available as a guide in determining the need and urgency for subsequent public health nursing follow-up

Results

The total number of persons x-rayed was 52,137, of whom 51,529, or 99 per cent, were fifteen years of age or over At first glance this would appear to represent 78 per cent of the residents fifteen years of age or over in Niagara Falls Actually, however, it is estimated that only 46,095 of these were actual residents of the city, and the remainder, for the most part, were nonresident employes in the industries which were surveyed as part of the total survey Of the estimated 66,000 resident adults, 5,000 employed in industry had been x-rayed a short time prior to the beginning of this survey, and it was not thought necessary to insist on their being x-rayed again This left 61,000 resident adults eligible for x-ray of which the 46,095 x-rayed during the survey represent 75 4 per cent The tabulation of the x-rayed adult resident population according to age and sex is based on this figure and is shown in Table 1 and Fig 1

For both sexes, the highest percentage x-rayed was in the age group fifteen to twenty-four years (84 8 per cent) and the lowest in the age group forty-five years of age and over (52 6 per cent)

Results

The total number of persons x-rayed was 52,137, of whom 51,529, or 99 per cent, were fifteen years of age or over At first glance this would appear to represent 78 per cent of the residents fifteen years of age or over in Niagara Falls Actually, however, it is estimated that only 46,095 of these were actual residents of the city, and the remainder, for the most part, were nonresident employes in the industries which were surveyed as part of the total survey Of the estimated 66,000 resident adults, 5,000 employed in industry had been x-rayed a short time prior to the beginning of this survey, and it was not thought necessary to insist on their being x-rayed again This left 61,000 resident adults eligible for x-ray of which the 46,095 x-rayed during the survey represent 75 4 per cent The tabulation of the x-rayed adult resident population according to age and sex is based on this figure and is shown in *Table 1 and Fig 1*

For both sexes, the highest percentage x-rayed was in the age group fifteen to twenty-four years (84 8 per cent) and the lowest in the age group forty-five years of age and over (52 6 per cent)

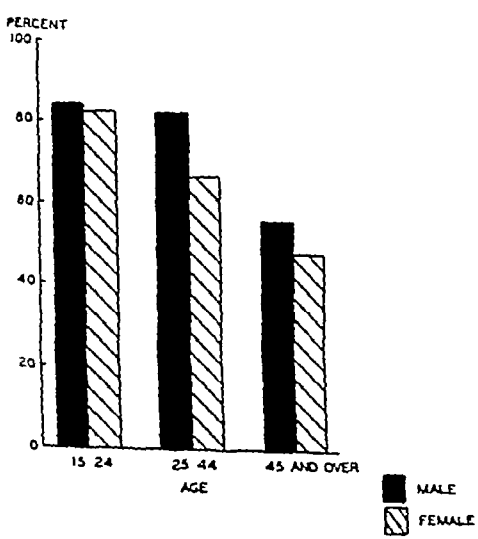

FIG 1 Percentage of estimated population x-rayed by age and sex

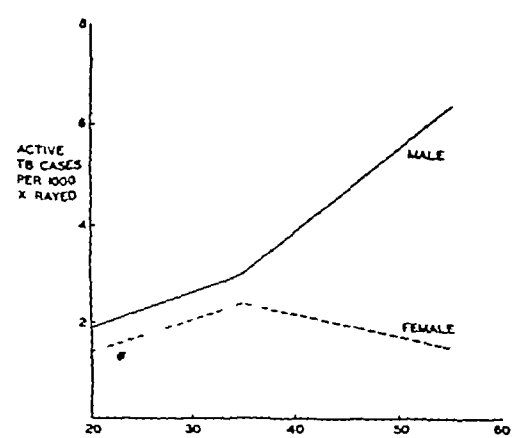

FIG 2 Prevalence of active tuberculosis by age and sex

TABLE 3.—DISTRIBUTION OF CASES CLASSIFIED PROBABLY ACTIVE TUBERCULOSIS BY SEX AND STAGE OF DISEASE

Sex	Total Cases Probably Active Tuberculosis		Minimal		Moderately Advanced		Far Advanced	
	Number	Per Cent	Number	Per Cent	Number	Per Cent	Number	Per Cent
Both sexes	150	100 0	119	79 3	28	18 7	3	2 0
Male	107	100 0	85	79 4	19	17 8	3	2 8
Female	43	100 0	34	79 1	9	20 9	0	

In terms of numbers, however, the best participation was obtained in the age group twenty-five to forty-four, in which about 21,000 out of 28,000 eligibles were x-rayed For all age groups the percentage of males x-rayed was higher than for females This was particularly marked in the group twenty-five to forty-four, in which about 84 per cent of the males were examined as against 68 per cent of the females This excess of males over females may be due to the fact that industry in Niagara Falls employs a large percentage of the male population where it is more easily reached by survey methods

The prevalence of tuberculosis based on survey film interpretations is shown in Table 2 and Fig 2 Among all the adults x-rayed, 481, or 0 9 per cent, showed x-ray evidence of tuberculosis Of these, 150, or 0 29 per cent of the total x-rayed, were classified as "probably active pulmonary tuberculosis" For all ages combined, the prevalence of probably active pulmonary tuberculosis was two times higher among males than among females—0 37 per cent as against 0 19 per cent In those over forty-five years of age, the rate among males (0 63 per cent) is almost four times that of the females (0 15 per cent) and serves to emphasize once more the seriousness of the problem among older males and the need for ever-increasing efforts to reach this group

The distribution of the probably active cases of tuberculosis by stage of disease is shown in Table 3 Of the 150 so classified, 12 showed pleural effusion and are provisionally classified as "minimal tuberculosis" By stage of disease, 79 per cent were minimal, 19 per cent moderately advanced, and 2 per cent far advanced There appear to be no significant sex differences Only 12, or 8 per cent, of the 150 cases designated as probably active tuberculosis had been previously reported and thus known to the health department

While chest x-ray surveys are organized and conducted for the primary purpose of finding hidden cases of tuberculosis, the importance of the nontuberculous, intrathoracic conditions discovered through this means cannot be minimized In this era of increasing public health significance of heart disease and cancer control, to mention just two problems, the finding of conditions other than tuberculosis assumes steadily greater importance to the community as well as to the individuals concerned

Table 4 shows the distribution of nontuberculous, intrathoracic conditions by sex A total of 630 persons, or 1 2 per cent of the total x-rayed, showed x-ray shadows suggestive of nontuberculous pathology, of whom 389, or 0 8 per cent, showed evidence of heart disease and 169, or 0 3 per cent, pulmonary fibrosis There were also 17 whose x-rays showed shadows which were thought to be due to intrathoracic tumor

A tabulation of probably active tuberculosis found in industrial workers and in the rest of the community is shown in Table 5 and Fig 3

Of the total of 28,955 adult males x-rayed, about one half were employed in industry A study of Fig 3 indicates that the prevalence of active tuberculosis below the age of forty-five is higher among male industrial workers than among males in the rest of the community Above the age of forty-five no significant differences are noted between these groups

Of the total of 22,574 females x-rayed, 3,318, or about 15 per cent, were employed in industry When the prevalence of probably active tuberculosis among female industrial workers is compared with the females in the rest of the community, it appears that only below the age of twenty-five is there any clear indication that active tuber-

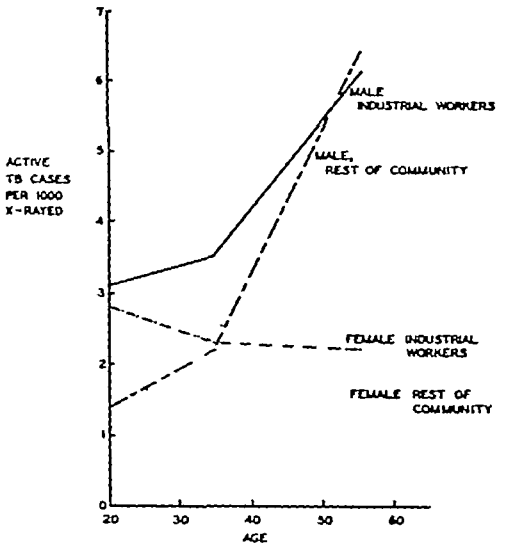

FIG 3 Prevalence of active tuberculosis by age, sex, and occupational group

culosis may be more prevalent among females in industry

The findings noted above suggest that male industrial workers in the younger adult ages are subject to a risk from tuberculosis which is greater than that observed among males not employed in industries Female workers below the age of twenty-five employed in industry appear to have a higher prevalence of tuberculosis than is found among nonindustrial female workers At all other ages there appears to be no difference in tuberculosis prevalence between females in industry and those not so employed

Whereas tuberculosis is significantly more prevalent in industry, such is not the case for nontuberculous intrathoracic conditions (Table 6) No significant differences in the rates for nontuberculous conditions were found in industry as compared to the rest of the community, with the exception of heart disease. In this condition, the rate is higher in the community than in industry A reasonable explanation for this might be that, unlike tuberculosis, most individuals with heart disease have symptoms that soon necessitate their severance from employment, especially in manufacturing industries

Results of Initial Follow-Up with Large Films

As shown in Table 7, of 481 individuals whose survey films showed evidence of definite or suspected tuberculosis, 332 had also been x-rayed on 14- by 17-inch films by the time the survey was finished Of the 320 with survey film diagnoses of definite tuberculosis, the large films showed agreement in 294, or 92 per cent The large film diagnosis agreed with the survey film diagnosis in 86 per cent of those whose survey film diagnosis was probably active tuberculosis and in 95 per cent of those whose survey film diagnosis was probably inactive tuberculosis Only 19 of the 332 x-rayed for a second time were negative on the large films The greatest percentage of disagreement occurred among those whose survey film diagnosis was probably active minimal tuberculosis

It cannot be emphasized too strongly that nei-

ther the survey film diagnosis nor the large film diagnosis may in any way be considered as a *final* diagnosis or determination of activity In having the physician with the x-ray units, who should be experienced and qualified in the interpretation of chest x-ray films, make a *tentative* diagnosis and estimate of clinical status on the basis of the examination of a small or a large film, the purpose is to provide an index to public health workers for priority of follow-up and also, if for some reason follow-up is not carried out, to have some idea of what type of tuberculosis remains unsupervised in the community The final diagnosis and determination of clinical status, obviously, is reached by thorough study by all accepted methods through effective follow-up In other words, the survey points to the need for effective follow-up Effective follow-up implies nursing visits and study of the patients by all the methods, including additional clinical, x-ray, and laboratory study, in order to reach a final definite diagnosis

Summary

1 A total adult population chest x-ray survey of Niagara Falls was completed in eight weeks, during which 52,137 individuals were x-rayed, of whom 99 per cent were fifteen years of age or older

2 It is estimated that 75 4 per cent of the resident adults eligible for x-rays were examined

3 The highest percentage of adults x-rayed was in the age group fifteen to twenty-five and the lowest in those over forty-five. The largest number of individuals examined was in the age group twenty-five to forty-four

4. In all age groups, more males than females were x-rayed

5 On the basis of survey film interpretations, 481, or 0 9 per cent, of the films showed evidence suggestive of definite or suspected tuberculosis Of these, 150, or 0 29 per cent of the total x-rayed, were considered tentatively to have probably active tuberculosis The rate of probably active tuberculosis was twice as high among males as among females

6 In both sexes and in all the age groups, the rate of probably active tuberculosis was highest among males forty-five years of age or older This emphasizes the seriousness of the problem among older males and points to the need for increasing all efforts to x-ray the chests of all individuals in this high prevalence group

7 Only 12, or 8 per cent, of the probably active cases had been reported previously, the remainder, or 138, therefore, were new to the Health Department

8 By stage of disease, the probably active cases were classified as follows minimal, 79 per cent, moderately advanced, 19 per cent, far advanced, 2 per cent

9 Nontuberculous intrathoracic conditions were diagnosed in 630 individuals, for a rate of 1 2 per cent Of these, 389, or 0 8 per cent, were suggestive of heart disease, and 169, or 0 3 per cent, of pulmonary fibrosis In 17 films, abnormal shadows were found which were interpreted as probably being due to intrathoracic tumor

10 Industrial employes showed a higher rate of probably active tuberculosis for both sexes, and this was more pronounced in males than in females

11 Follow-up 14- by 17-inch film examinations were possible during the survey for 69 per cent of the persons whose survey films showed definite or suspected tuberculosis Of the 320 persons x-rayed on 14- by 17-inch films, whose survey films showed definite tuberculosis, the large films showed agreement in 294 cases, or 92 per cent

MAY 8-12, 1950
HOTEL STATLER, NEW YORK CITY

DIARRHEA OF THE NEWBORN

An Approach to Control Through Minimum Standards of Nursery Care*

RAY E TRUSSELL, M D , Albany, New York

(*From the Albany Medical College and the New York State Department of Health*)

ALTHOUGH diarrhea of the newborn was not reportable in New York State until the middle of 1946, a total of 28 nursery epidemics came to the attention of the State Department of Health during the six-year period, 1942 through 1947 There were 618 ill infants with 62 deaths These data are known to be incomplete

Because of the continuing development of such epidemics, the need for a control program seemed evident The clinical manifestations which were grossly similar in the various outbreaks were conceivably due to a variety of causative agents in the light of past experience The mechanism of spread sometimes seemed evident but often was not detectable through epidemiologic study The mortality rate in the various outbreaks varied from 0 to 50 per cent with inadequate criteria for prediction of the ultimate outcome Thus, any approach to control had to be partly specific and partly general and aimed at preventing the introduction and spread of infection in hospital nurseries The adoption and application of minimum standards for nursery care of newborn infants was the logical answer to the problem in the light of current knowledge

The standards adopted by the Public Health Council were based on the following

1 Epidemiologic studies in New York State and elsewhere
2 Recommendations of the American Academy of Pediatrics, Committee on Fetus and Newborn
3 Children's Bureau recommendations
4 Michigan Health Department's extensive research program on diarrhea of the newborn.
5 Medical Society of the State of New York, Council Committee on Public Health and Education
6 Hospital association representatives
7 Laboratory studies of formula sterilization
8 Individual consultants from many fields of interest

Briefly, the standards now embodied in the Sanitary Code require terminal "sterilization" of the formula in individual feeding bottles with nipple and cap attached, certain principles of isolation, the use of the "suspect" nursery system for observing infants with suspicious signs of illness, individual care for each infant with his own equipment, careful handwashing by physicians and nurses after coming in contact with any infant, adequate space for nursing care, adequate numbers of nursing personnel, and a limit on the number of infants in each nursery

The regulations are brief and allow for considerable flexibility in their application Detailed standards were not utilized because upstate hospitals and maternity homes vary in bassinet census from two to more than 70 and must meet the minimum standards with existing facilities and community resources The regulations have been the subject of favorable editorial comment, have been approved of by the individual members of the American Academy of Pediatrics, Committee on Fetus and Newborn, and have been sent by this committee to its subcommittees in other states and in certain territories with the suggestion that similar legislation be secured Thus, the New York State program has emerged as an effort attracting national attention Its success or failure depends on the medical, nursing, and administrative staff of each hospital in the upstate area

Initiation of the Program

During the last nine months of 1948, the Medical Society of the State of New York and the State Department of Health jointly sponsored an educational program to acquaint hospital administrators, physicians, and nurses with the newly adopted standards and to point out various feasible ways of meeting the requirements of the Sanitary Code which became effective January 1, 1949 Letters of explanation, reprints, suggested procedures, and questionnaires planned as means of self-evaluation were distributed Eleven regional institutes were held which were attended by 982 administrators, practicing physicians, nurses, and health officers Consultation was given by a hospital nurse consultant and/or an epidemiologist in approximately 120 hospitals A series of newspaper and radio announcements were released to acquaint the communities with the impending changes and the ways in which

* Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Public Health, Hygiene and Sanitation, May 5 1949

* This presentation is a progress report and the introductory remarks are merely a summary of more detailed discussions given elsewhere

they could assist their hospitals The emphasis throughout has been on simplification of technics, use of existing equipment, and careful study of each hospital's problem to avoid expenditures beyond the hospital's needs and the community's resources

Scope and Magnitude of the Hospitals' Problems

As crude measures of the scope and magnitude of the hospitals' problems, data collected in 1948 through questionnaires from 224 or 99 per cent of the 226 upstate hospitals and maternity homes with nurseries for newborn infants can be quoted The purpose here is to illustrate certain gross needs in the total upstate hospital group No attempt has been made to break the data down according to certain subclassifications of hospitals No criticism is intended of hospitals which were in their overcrowded and understaffed status due to the increasing demand for hospital deliveries Many hospitals were doing a splendid job of maintaining precautions for protection of the newborn before the control program was inaugurated

If certain of the requirements of Regulation 35 are used, the status of the 224 hospitals can be summarized as follows (Table 1)

From this tabulation it can be seen that overcrowding, understaffing, lack of handwashing facilities, equipment and bathing and dressing tables common to several infants in a nursery, and lack of protection afforded by terminal heating of formulas were problems of considerable magnitude in the 224 hospitals

Transition Period

When the Public Health Council adopted the new standards, it was with the full realization that reconstruction is costly and time-consuming and that additional nurses cannot be trained and employed overnight For these reasons, provision was made to defer enforcement of the requirements specifying floor space allowances, maximum number of infants per nursery, and maximum number of infants to be given care by one nurse until January 1, 1951, if the hospital administrator and the responsible health officer agreed that such were necessary

Up to the present time 108 hospitals have been granted deferments to the average space requirements for each infant Of these 53, or 49 per cent, asked for a maximum deferment of two years, although several have definite building programs underway or financially assured The remaining 55, or 51 per cent, are making the necessary changes in less than two years

In addition, 84 have been granted deferments to the requirement that no nursery shall house more than 12 infants Of these 40, or 47 7 per cent, were for the maximum deferment of two years

Finally, 68 have been granted deferments to the requirement that no nurse shall give care to more than 12 infants Of these, 36 or 52 9 per cent, were for the maximum deferment of two years

Thus, about 50 per cent of the hospitals granted deferments of any type have arranged already to be in complete compliance in less than two years Many other hospitals made the necessary changes before last January

It should be pointed out that many of these situations requiring deferments were borderline, and the hospitals requested deferments as precautionary measures The attitudes of the hospital administrators and medical and nursing staffs have been splendid Excellent cooperation has been an almost universal experience for those of us who have been working with the hospitals during the last year Many hospitals have made outstanding efforts not only to meet the minimum standards but also to include in their nursery policy and procedures additional detailed recommendations of the American Academy of Pediatrics

TABLE 1.—Status of 224 Hospitals

Requirement	Number Meeting Requirement	Number Not Meeting Requirement	Total	Per Cent Not Meeting Requirement
Nurse–baby ratio of 1 12 around the clock	150	74	224	33 0
24 square feet of floor space per infant or cubicles	77	147	224	65 6
Not more than 12 infants per nursery	111	101	222	45 4
Intercommunicating nurseries prohibited	193	28	221	12 7
Isolation facilities—permanent or temporary	209	8	217	3 7
Individual equipment for each infant except for weighing scales	105	118	223	52 8
No common carriers for bassinets	143	80	223	35 9
Handwashing facilities in *all* nurseries	166	57	223	25 6
Formula in individual feeding bottle at time of preparation with nipple and cap attached	176	46	222	20 7
Terminal heating of formula	93	128	221	57 8
Bulk storage of formula prohibited	170	54	224	24 1
Separate nurses for sick and well infants	191	32	223	14 3
Individual care of infants	100	123	223	55 2
Common bath table prohibited	99	123	222	55 4
Common dressing table prohibited	100	123	223	55 2

Future Policies

Having passed through this initial educational effort and the period of change-over in the hospitals as far as it has progressed, what of the future? The enforcement of the minimum standards for nursery care in each hospital is now the responsibility of the full-time health officer or commissioner of the city, county, or district within whose jurisdiction the hospital is located Every effort will be made to continue the program on an educational level In so doing at least three resources will be utilized beyond those locally available through the health officer (1) consultation services from the State Department of Health and (2) distribution of appropriate manuals of recommended procedures For example, the newly adopted official manual of recommendations for care of the newborn published by the American Academy of Pediatrics is being sent to every hospital and every health officer who will be working with these hospitals (3) A demonstration and training center has just been organized in the Brady Maternity Hospital in Albany This training center will be utilized first, to give public health nurses, who will be working with hospitals, and health officers actual experience in carrying out simplified techniques and meeting the Sanitary Code requirements, second, to give short-term intensive training to nurses from hospitals in need of assistance, and third, to demonstrate to health officers and other physicians the recommended procedures in actual practice This center is designed to meet an immediate need and will not be a substitute for the long-term training so desirable for well-trained supervisory personnel

Evaluation

It is impossible at this time to evaluate the long-range results of this control program Approximately a year has elapsed since the initiation of the educational program described There were two epidemics in progress last May, 1948, when the regional institutes were being held In July, 1948, there was one bizarre explosive outbreak which was confined to breast-fed infants and was self-limiting and nonfatal The same hospital recently had another nonfatal outbreak No epidemics have been reported from the other 225 hospitals and maternity homes in the past twelve months No lasting importance can be attached to this analysis at present Similar epidemic-free periods have occurred in the past At present, it can be said only that the situation appears encouraging If it remains favorable, it will be the result of a continuation of the wholehearted cooperation of administrators, physicians nurses and health department personnel which has been so evident up to the present time

Discussion

Harold Abramson, M D , *New York City* —It is indeed a pleasure to discuss Dr Trussell's progress report on the New York State Department of Health's program for the prevention of diarrheal disorders among newborn infants in obstetric nurseries The planning and effort involved in conducting such a campaign is considerable. Almost fifteen years have elapsed since the attention of public health workers was first called to the prevalence of fatal diarrhea in newborn infants Since that time, interest has heightened in the problems of newborn infants and in the improvement of their medical and nursing care Sanitary Code regulations have been rapidly enacted placing the conduct of maternity and newborn nursery services under the direct jurisdiction of local and state health departments Suggested standards have also been advanced by various national health organizations In the main, these regulations and standards have sought to establish practical methods of medical and nursing procedure and to prescribe certain minimal physical requirements and equipment to insure the safety of mothers and their babies in hospitals giving lying-in care

It will be noted that regulation of maternity services had its origin in cities such as New York and Chicago From this broad local base, supervision has pyramided with separate laws of control at the state level These codes have been topped by suggested standards circularized by national organizations such as the American Academy of Pediatrics and the Children's Bureau A joint committee of the American Hospital Association and the American Public Health Association is now also engaged in forming for distribution suggested minimal recommendations for the control of infection among newborn infants in hospitals Still another committee of the American Hospital Association is attempting to standardize formula preparation procedures

With this multiplicity of regulations, suggested standards, and committees, the thought arises that perhaps the eventual over-all result will be one of confusing, rather than clarifying the basic principles underlying the care of the newborn The problem could perhaps be approached more efficiently by setting up a central advisory committee of interested national health organizations to draw up acceptable basic standards and to coordinate the efforts of the separate committees A vertical organization would, therefore, be established representing the best thoughts on the problem Following the formulation of standards at the national level, the material could be adapted for use at the state level and finally tailored to suit needs at the local level.

Furthermore, it has been our experience that the various plans that have been advanced seem restricted in scope and place main emphasis on the control of the diarrheal diseases of newborn infants

The prevalence of infection, such as sepsis, impetigo, respiratory disorders, and thrush seems to have been overlooked In addition, the special problem of the premature infant has not been brought to the fore The care of mothers is also not sufficiently stressed

It would appear that more comprehensive programs are in order The projects should have horizontal, bilateral extensions to include the prenatal care of mothers at one extreme and the postpartum care and follow-up of mothers and their babies at the other extreme In between, the goal to be achieved is the safe routing of mothers and babies through the hospitals The psychologic relationship between mother, baby, and father should be borne in mind to maintain the family unit Whether the small nursery unit or the rooming-in system of care is best suited to achieve this end must be left to the test of time At any rate, with early ambulation, the mother should participate more and more in the care of her infant in the hospital

A modern and completely equipped physical plant is, of course, desirable But even more important is the establishment of safe, practical, and closely supervised medical and nursing policies and procedures As has been indicated by Dr Trussell, the continued training of physicians, nurses, and other hospital personnel in the care of mothers and babies should be weighted heavily It has been our experience in New York City that there are two items of paramount importance that cannot be spelled out or written into any code or system of standards They are *an understanding of the quality of care* and *the art of its administration* It is here that education plays so important a role This phase of the project is one of long-term instruction and training

One would be remiss if one failed to include in this discussion the need for better methods of study and differentiation of the diarrheal disorders of the newborn, as well as other communicable disorders to which newborn infants are peculiarly susceptible. Main reliance in the differentiation of the diarrheal diseases must at present be based on clinical criteria. The cases must, furthermore, always be considered in relationship to possible points of origin of infection and methods of spread. Postmortem examinations should be more thorough

Except in instances of infection by organisms of the Salmonella or Shigella groups, present bacteriologic procedures offer no aid in diagnosis There are a limited number of laboratories that can carry out virus studies of the type required in investigations of the diarrheal diseases The few reports that have been published thus far have not conclusively indicated a causal relationship of outbreaks to the agents isolated Progress in the prevention and control of the diarrheal diseases will be impeded until suitable laboratory technics are evolved for differential diagnosis In the future, projects designed to control the spread of diarrheal and other infections in newborn infants should provide for adequate laboratory investigations

NEW YORK STATE MEDICAL LIBRARY

Doctors of New York State are reminded of the facilities of the State Medical Library at Albany They are invited to visit, telephone, or write to the Library where a trained staff of librarians will take care of their requests

Upon request, a copy of the regulations will be sent, which lists the services of the Library, including the compiling of bibliographies, sending material on specific subjects, or filling requests for definite book or journal references

A collection of over 57,000 books and the receipt of approximately 600 current medical journals enable the Medical Library to offer a real service to the doctors of the State

Letters may be addressed to Miss Maude E Nesbit, Librarian, New York State Medical Library, Education Building, Albany 1, New York.

THE PROBLEM OF CEREBRAL PALSY

MORTON L LEVIN, M D , I JAY BRIGHTMAN, M D , and EDITH J BURTT,* Albany, New York

(From the Division of Medical Services, New York State Department of Health)

CEREBRAL palsy has been defined as "a group of conditions which affect the control of the voluntary motor system and which have their origin in lesions of various parts of the brain."[1] The symptoms have been classified under five categories, namely, spasticity, athetosis, ataxia, rigidity, and tremors It has been estimated that approximately one third of the cases are associated with mental deficiency The extent of involvement and the degree of functional loss vary considerably among the afflicted persons Formerly, the condition was looked upon as one of hopeless invalidism, and unfortunately both patients and families harbored a sense of shame in connection with it More recently, great claims have been made regarding remarkable results which might be achieved with cerebral palsy patients if only the necessary personnel and facilities were made available As a result, there have appeared many arbitrary statements regarding the needs of cerebral palsy patients and the responsibility of official and voluntary agencies at the State and local levels to meet these needs Unfortunately, there have been little data available regarding the indicated scope and the actual potentialities of any large-scale program.

Perlstein has estimated that seven persons with cerebral palsy are born every year for each 100,000 of the population, and that six of these survive past the sixth year of life [2] This formula cannot be considered as generally applicable because no supporting data have ever been published and because it does not take into consideration the age distribution of the population and other factors which affect the birth rate

During the latter half of 1948, a survey was conducted in Schenectady County for the purpose of more clearly defining the problem of cerebral palsy with reference to its incidence and prevalence, variations in morphologic and functional types, sociologic aspects, and special needs for medical and related services This survey was carried out by the New York State Department of Health, with the State Departments of Mental Hygiene, Education, and Social Welfare serving in an advisory capacity Extra funds were made available by the Joint Legislative Committee to Study the Problem of Cerebral Palsy Many Schenectady City and County official and voluntary agencies cooperated by making their records on cerebral palsy patients available to the survey staff Foremost among these was the Eastern New York Orthopedic Hospital-School, popularly known as Sunny View, which also provided the facilities for the special clinics held in connection with the study

The purpose of this article is to highlight some of the findings of the Schenectady County survey and to point out the scope of the State program during the current fiscal year

Schenectady County Survey

Prevalence Study —The study of prevalence of cerebral palsy in Schenectady County was conducted in two steps First, all cases known to any medical or welfare agency at the State or local level were collected in a roster of known cases In addition, questionnaires were sent to each of the physicians practicing in the County, inquiring of cases of cerebral palsy known to them All the names obtained from these various sources were checked for duplications Each unduplicated case was then checked to ascertain whether the named person was still residing in the County

This procedure revealed that a total of 125

* By invitation.

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Public Health Hygiene and Sanitation May 5 1949

* As of July 1 1948, total population estimated by Office of Vital Statistics New York State Department of Health. Age distribution is that found in sample population comprising 16 4 per cent of estimated total population.
† Per 100 000 population.

patients with a diagnosis of cerebral palsy were known to be residing in the County at the time of the survey As the Schenectady County population in 1948 was estimated at 137,000, the prevalence rate of known cases is 91 per 100,000 population (Table 1)

The *second step* was a canvass of a representative sample of the population for the purpose of uncovering cases not known to any physician or agency In the City of Schnectady and in the adjacent villages of Scotia, South Schenectady, and Carman, the original canvass plan included every fourth house or apartment In the rural areas of the County, patches of territory corresponding to about 25 per cent of each township were selected at random, and all dwellings within each patch were included in the plan

A staff of 18 medical students was recruited during their summer vacations for the purpose of interviewing the families residing in the selected houses The prepared questions were broad in scope and were designed to discover all persons who might possibly have cerebral palsy The exact determination of the diagnosis was left to subsequent medical examination.

Because the medical students were available only during the summer months, it was not possible to cover the total of 25 per cent of the population called for in the original plan However, the investigation obtained adequate information concerning 22,528 persons, or 16 4 per cent of the estimated total population Because of its random method of selection, this sample was considered sufficiently large to be representative of the total County population. The age distribution of individuals in the canvassed groups did not differ in any significant way from that of Schenectady County's population as recorded in the 1940 census and was also essentially similar to that of New York State The representativity of this 16 4 per cent sample was further indicated by the fact that the canvassed area was found to include the residences of 20, or 16 per cent, of the 125 already known cerebral palsy cases

Fourteen cerebral palsy persons not previously known as such to any of the physicians or agencies cooperating in the study were discovered by the investigators, the exact diagnosis being confirmed by later medical examination If the sample is truly representative, it can be assumed that, had the entire county been canvassed, a total of six times that number, or 84 previously unknown cases of cerebral palsy, would have been found Therefore, the estimate for the total number of cerebral palsy cases in the County is 125 known, plus 84 unknown cases, or 209 cases in all This is equivalent to a prevalence rate of 152 per 100,000 population.

A puzzling feature of the age distribution of known cerebral palsy cases is the relatively low prevalence in the first few years of life. One would ordinarily expect that a condition which is most often congenital would be found with maximum frequency in the group under five years of age If all cases were diagnosed and reported during the first year of life, the prevalence would be highest at age one and would decrease in subsequent years in proportion to whatever excess mortality exists among cerebral palsy patients as compared with all other individuals Yet, the maximum prevalence of known cases in this survey was found in ages five through nine years, in which the rate was 440 per 100,000 population of that age The rate among children under five years was only 126 per 100,000, or less than one third as great

The most apparent explanation for this difference is that a high proportion of cerebral palsy cases are either not diagnosed or not reported to any medical agency during the first five years of life Diagnosis at ages under one year is difficult Parents often ignore or minimize any neuromuscular difficulties which they may notice in the infant in the hope that he will outgrow them, or, on the other hand, may try to shield the child from any public agency because of a sense of shame Yet, the attempt made in this survey to discover such cases was only partly successful The survey did uncover three new cases in each of the younger age groups, under five years, five to nine years, and ten to fourteen years However, when the total number of cases was estimated for each age group, the deficiency of cases in the youngest age group was not significantly offset The prevalence rate for total estimated cases in the "under five" group was 267 per 100,000, still less than half that for the five-to-nine-year group which was 634

In establishing the criteria for the diagnosis of cerebral palsy for the purpose of this study, it was decided to limit this designation to those patients whose symptoms had been manifested before the age of twelve An analysis was made to determine the relative incidence of congenital causes of cerebral palsy and of postnatal causes such as meningoencephalitis or trauma Information regarding the time of onset of the symptoms and the relationship to any postnatal factor was available for 121 patients Of these, only ten, or 8 3 per cent, had a history of manifestations of cerebral palsy appearing subsequent to cerebral trauma or to an infectious disease suggesting meningoencephalitis In nine of these ten cases, the causative factor appeared after the fifth year In the remaining 111 cases, the symptoms appeared at birth or within the first six months.

When the prevalence data were corrected by

omitting cases developing postnatally, there was still a marked discrepancy between the prevalence of congenital cases under five years and those between five to nine years The rates per 100,000 population were 251 and 591, respectively It appears that the figure of 591 per 100,000, or 5 9 per 1,000, is close to the true incidence of the disease among newborn infants and that the lower figure for prevalence in the under-five group, is observed only because of failure to detect cases despite the direct type of survey conducted in Schenectady County

The Socioeconomic Aspects—The families of 104 patients with cerebral palsy were visited by trained medical social workers for the purpose of determining the social and economic background in which cerebral palsy occurred and the effect of the disease upon the adjustment of the patient to his disability and to his environment For the purpose of obtaining control data, similar interviews were held with an additional 109 families, 30 of which had no physically handicapped member and 79 of which had one or more members with a handicapping defect other than cerebral palsy

Analysis of the economic status of the families revealed that cerebral palsy was no respecter of economic level and that the financial resources of the cerebral palsy families were similar to those of both control groups The occupations of the chief wage-earners and the educational backgrounds of both parents were likewise similar in distribution in the cerebral palsy and the control families In general, the families of both the cerebral palsy patients and the families with other physical handicaps paid somewhat smaller amounts for monthly rentals than did the so-called "healthy" families This may be related to the large portion of family budgets utilized for the care of disabled members Even many of the higher income group reported that the costs of providing care for the cerebral palsy patient had resulted in serious strain on the family economy

Only 22 per cent of the patients with cerebral palsy who were five years of age or older were or had been able to attend regular school and maintain their proper grade Another 17 per cent were or had been able to attend regular school but had fallen two or more years behind the grade expected for their chronologic age Thirty-four per cent of the patients were or had been assigned to special school classes or committed to special institutions because of serious mental or physical incapacity, and 27 per cent had never been able to attend any school whatsoever As would be expected, adjustment to school was related to the severity of involvement Fifty-three per cent of those with mild handicaps were attending or had attended regular school in their proper grades compared to only 13 per cent of those with severe handicaps On the other hand, only 6 per cent of those with mild handicaps had never been able to attend school, contrasted to 35 per cent of those with marked handicaps

Regarding employment, 21 per cent of the cerebral palsy patients over twenty years of age were found to be working full time, 17 per cent part-time or irregularly, and 62 per cent not at all It was observed by the interviewers that employability in general was dependent not only upon the extent and degree of involvement but also upon the type of personality and emotional adjustment to the disability There were several patients with considerable loss of function who were able to make useful citizens of themselves, either by taking care of households or by managing to maintain some form of self-support In contrast, there were several persons with relatively slight degrees of disability who could not maintain a degree of self-sufficiency because of a severe emotional reaction to the defect or because they tended to use the defect to protect them from facing the realities of life

The Clinical Picture of Cerebral Palsy—An evaluation was made regarding the extent of involvement and degree of functional loss for those cerebral palsy patients appearing on the roster This roster contained 147 names, including the 125 patients who had been known to the various medical and welfare agencies, the 14 newly discovered patients encountered during the canvass of the sample area, and nine additional patients who became known to the staff during the course of the survey as a result of information submitted by interviewed persons In 79 instances the evaluation was based upon a physical examination arranged especially for this purpose and conducted by a physician with special training in cerebral palsy Eight evalua-

TABLE 2—CLASSIFICATION OF 132 CEREBRAL PALSY PATIENTS AND ANALYSIS OF SPASTIC AND RIGID CASES BY EXTENT OF INVOLVEMENT

Classification of 132 Cerebral Palsy Patients by Major Manifestation

Manifestation	Number of Patients
Spasticity	72
Rigidity	16
Athetosis	17
Ataxia	18
Indefinite	9
Total	132

Classification of 70 Spastic and 16 Rigid Cases by Extent of Involvement

	Spastic	Rigid
Monoplegia	2	0
Paraplegia (lower extremity)	14	0
Hemiplegia	37	9
Quadriplegia	19	7
Total	72	16

tions were made by the patient's private physician Forty-five patients did not have special examinations, but sufficient data for evaluation were available through clinic and hospital records or from sociologic interviews with the families Twelve patients were in State schools for the feeble-minded and one patient with epilepsy was in Craig Colony It was not possible to obtain sufficient data for an evaluation of two patients

The data are presented in Table 2 Of the 132 patients on whom adequate data were available and who were not in institutions, 72 showed spasticity, 16 rigidity, 17 athetosis, and 18 ataxia In nine instances, no specific classification could be assigned. Table 2 also includes an analysis of the spastic and rigid patients according to extent of involvement

Sixty-five, or 45 per cent, of the 145 patients were considered to be mentally deficient or to be so severely handicapped as to be unable to give evidence of satisfactory intelligence Twelve of these were in institutions for the feeble-minded, and 34 others had received low ratings in school psychometric tests The remaining 19 were rated as mentally defective because of serious retardation at school or obvious lack of mental development It is quite probable that in some instances patients with normal intelligence were unable to achieve satisfactory psychometric ratings or to demonstrate intelligent behavior because of serious physical defects

All of the 145 patients were reviewed from the viewpoint of what services were indicated to give the patient the best possible chance of maximum improvement The variety of services needed for cerebral palsy patients is extraordinarily complex including as it does many medical and other professional specialties in a wide range of outpatient, inpatient, educational, and institutional types of care The patients studied in this way were grouped into three categories (1) those who needed no services, (2) those whose needs could be met while they lived at home, and (3) those who required permanent or prolonged institutional or hospital care The data are summarized in Table 3

TABLE 3.—NUMBER OF CASES NEEDING NO SERVICES, OUTPATIENT SERVICES OR INPATIENT SERVICES (BY AGE)

Type of Services Needed	Total Patients	Under 5 years	5–9 Years	10–14 Years	15–19 Years	20 Years and Over
All	145 (100%)	17	46	21	12	49
Inpatient						
Hospital school	12 (8 3%)	2	4	2	2	2
Custodial institution	27 (18 6%)	2	7	5	2	11
Outpatient	93 (64 1%)	12	34	11	7	29
None	13 (9 0%)	1	1	3	1	7

1 Thirteen, or 9 0 per cent, of the 145 evaluated patients had such a slight degree of handicap or were so well-adjusted that they did not require any special services

2 Ninety-three, or 64 1 per cent, of the patients were believed to be able to profit by some form of outpatient service The cerebral palsy patient considered under this heading is one whose family can provide a suitable home condition for him and, if necessary, can assist him in taking care of his routine personal needs and whose physical and mental condition called for such services as periodic examination by an expert medical team, physiotherapy, occupational therapy, brace fitting, speech therapy, psychometric testing and follow-up, medical social service, and vocational training The availability of these services offers the patient a chance to achieve maximum rehabilitation while remaining in his own home environment and, in many instances, allows him to carry out activities such as attending school and obtaining vocational training or actual employment

As indicated in Table 4, in almost two thirds of the cases it was believed that such outpatient services might best be combined with schooling for patients of school age or for those over twenty years of age in need of vocational training From the psychologic viewpoint, it was felt that, wherever possible, the children should be assigned to regular school classes This was considered feasible in 21 instances Special classes, because of serious mental retardation or severe physical handicap, were indicated in 33 instances Special vocational training classes were indicated for

TABLE 4.—TYPE OF OUTPATIENT SERVICES NEEDED BY 93 CEREBRAL PALSY PATIENTS ACCORDING TO AGE GROUP

	Total	Under 5 Years	5–9 Years	10–14 Years	15–19 Years	20 Years and over
All Cases	93	12	34	11	7	29
Outpatient services associated with schooling	60		30	11	6	13
Regular class with physiotherapy	19		11	6	2	
Special cerebral palsy class	22		18	4		
Class for mentally retarded	3		1	1	1	
Vocational training	16				3	13
Outpatient services for patients below or above school age or unable to attend school	33	12	4*		1	16

* Includes three patients temporarily unable to receive any schooling because of medical status and one patient whose phy sical incapacity necessitated home tutoring.

16 patients, three of whom were in the fifteen-to-nineteen-year age group and 13 of whom were twenty years or older

The remaining 33 patients who were considered capable of benefiting from ambulatory services were either below or above school age or, for various reasons, were unable to attend school. It should be pointed out that the need for ambulatory services will be increased when patients requiring prolonged hospitalization are referred to ambulatory services when such hospitalization is completed. Many may refuse hospitalization, and then the need for ambulatory services would be increased immediately.

3. Prolonged hospitalization for periods ranging from three months to several years was recommended for 12 patients with cerebral palsy. Such hospitalization was prescribed when special orthopedic surgery was indicated or when it was considered that the amount of muscle training, physiotherapy, and speech analysis required was so intensive that possible benefit might be obtained only by placing the child in a hospital. Obviously, upon the completion of such treatment these patients would be referred for continued ambulatory service.

Custodial care was recommended for 25 patients with serious degrees of feeble-mindedness and also for two patients with normal mentality but with physical disabilities so great as to make care at home impracticable. Twelve of the patients with serious mental insufficiency were already confined to State schools for the feeble-minded. The survey revealed 13 other similar patients for whom such institutional care was immediately desirable. There were eight additional instances in which home care for feeble-minded cerebral palsy patients seemed adequate for the present but for whom it appeared likely that such care could not be provided for any considerable period in the future and that institutionalization would eventually be necessary.

Of the two patients with normal mentality for whom custodial care seemed indicated, one had epilepsy and was already confined at Craig Colony. In addition, there were two patients with similar clinical conditions for whom care was being adequately provided at the time of the survey but who would require custodial care in the near future when it seemed likely that the parents or other relatives would no longer be able to provide for them.

Comment

If the observations made in Schenectady County may be considered as applicable to the State as a whole, the total number of patients with cerebral palsy in New York State would be estimated at 22,000. Although these statistics comprise the most reliable data available at the present time, it must be considered that they are based upon findings observed in one county only. Before they can be considered as truly indicative of the total State figure, additional surveys must be conducted in one or two additional counties.

Even allowing a considerable degree of error in the estimated State total, the problem of cerebral palsy is still of major significance. On the basis of a birth incidence of 5.9 per thousand births, there are approximately 1,500 children born with cerebral palsy each year in this State, of whom, according to Phelps' estimate, approximately 200 die within the first five years of life. Of the remaining 1,300, 8 per cent, according to the Schenectady data, are only slightly handicapped, leaving an increment of approximately 1,200 individuals moderately or severely handicapped by cerebral palsy each year.

It is of interest to compare this estimate of cerebral palsy incidence with the corresponding data for recorded cases of poliomyelitis. During the five years from 1944 through 1948, including the epidemic year of 1944, there was an annual average of 2,845 cases of poliomyelitis reported. Published data indicate that 3 per cent of poliomyelitis cases die, and 14.5 per cent are left with moderate, marked, or complete residual paralysis. Assuming these figures to be generally applicable, there would occur an average annual increment of 412 patients with moderate or severe physical handicaps caused by poliomyelitis each year. This is approximately one third the number handicapped each year by cerebral palsy.

There is no doubt that the need for therapeutic and rehabilitative services for cerebral palsy patients is great. Parenthetically, it should be emphasized that the term "rehabilitation" is used here in its broadest sense of implying the training of the patient to utilize his neuromuscular resources to the greatest possible extent so that he may become wholly or partially self-sufficient and self-supporting. Obviously, in the case of congenital cerebral palsy patients, it could not be applied in its more narrow sense of meaning the restoration of a body to a previously normal condition, inasmuch as these patients had never known a normal status of body build and function.

Remarkable results have been achieved with formerly bedridden patients who, as a result of intensive therapy and sound adjustment, have become self-supporting. Such achievements cannot be expected for all cerebral palsy patients, particularly those with very severe physical handicaps or with serious mental deficiency. However, many of these now helpless invalids can be raised to an achievement level at which they can at least take care of their own personal needs. It makes a tremendous difference to the

family, school, or institution whether a patient can dress and feed himself Frequently, nothing short of an attempt at rehabilitation and training can demonstrate the real physical and mental potentialities of these patients

The New York State Department of Health has been spending about half a million dollars per annum for services to cerebral palsy children during recent years Direct services by the State have included medical or surgical care at the New York State Rehabilitation Hospital at West Haverstraw, diagnostic evaluation at special clinics, and physiotherapy by staff nurses and technicians Services are provided indirectly through State reimbursement to upstate counties and to New York City for the costs of care authorized for these patients by the county children's courts and by the New York City Department of Health Research studies in cerebral palsy are conducted either directly by the State Department of Health staff or by contract with medical agencies

For the fiscal year beginning April 1, 1949, the expenditures by the Department for cerebral palsy services are to be increased to over one million dollars Aside from increases in the costs of providing the services described above, the major items in this augmented program are the provision of $100,000 for outpatient diagnostic and therapeutic services, experimentation with cerebral palsy classes in cooperation with the State Education Department and provision of $250,000 for alterations to the Rehabilitation Hospital to allow it to care for 65 patients with cerebral palsy at any one time An important additional item is the provision of $25,000 to support training of physicians, physical therapists, occupational therapists, speech therapists, and other professional personnel in the management of cerebral palsy These funds are in addition to those expended by the State Departments of Mental Hygiene, Education, and Social Welfare in providing services to cerebral palsy patients or to their families

The program of the State Department of Health can be much enhanced by more active support by the full-time county and city health departments The local health officers are in a position to make a very significant contribution by expanding their current crippled children's programs The operation of cerebral palsy clinics might well be operated by the local health departments as a regular activity Cooperation with the local departments of education would result in the development of facilities for care within the school system for the large proportion of patients of school age who require frequent therapy The activities of the public health nurses and the medical social workers, when available, could be of great value in case-finding if adequate local facilities were available to which they might refer suspicious cases encountered during the course of routine activities They could also make a significant contribution in assisting the families and the patients themselves in carrying out therapeutic procedures at home, in making the best possible adjustment to the disease, and in obtaining maximal utilization of community resources in their effort for rehabilitation Very important is the field of public health education directed at acquainting the public with the nature of cerebral palsy so that a community effort may be made to assist the patients, and so that they may thereby not only be aided therapeutically, but will be allowed the best possible chance of establishing themselves as respected members of society

The costs of providing maximal therapy to all patients, along the lines indicated by the Schenectady survey, are so great and the chance of procuring and training sufficient personnel so remote that the combined efforts of State and local official and voluntary agencies are not likely to be able to meet these recommendations on a Statewide basis in the near future One of the most urgent needs is the development of new tests for the determination of educability and of potentialities of muscle training, so that concentration of effort can be directed at those patients found to be best prospects for rehabilitation. Continuation of intensive therapy after maximum improvement has been achieved is an unwise utilization of scarce personnel and facilities and deprives other patients from possible benefit

Summary

1 A survey of cerebral palsy patients in Schnectady County indicates that incidence of this disease is 5 9 per 1,000 live births, and the prevalence is 152 per 100,000 population. This would indicate that there are at least 22,000 persons with cerebral palsy in New York State However, the data are based on observations in one county only, and it would be necessary to repeat this survey elsewhere before the figures can be considered as truly applicable to the State as a whole

2 The occurrence of cerebral palsy bears no apparent relation to social, economic, and cultural factors Financial strain due to providing available care for the patients was evident at all but the highest economic levels

3 Twenty-seven per cent of patients five years of age or older had never attended school, and 34 per cent required special classes or institutional care Sixty-two per cent of the patients twenty years of age or older had never been

employed, and 17 per cent were employed either irregularly or on a part-time basis

4. The Schenectady County survey indicates that 9 0 per cent of cerebral palsy patients require no services, 64 1 per cent need services on an ambulatory basis, 8 3 per cent require prolonged medical treatment at a hospital-school, and 18 6 per cent should be placed in institutions for custodial care

5 In view of the limited number of qualified personnel and facilities available for the treatment of cerebral palsy patients, studies should be made to determine the ultimate which may be expected following the application of optimal treatment and a means determined to screen good prospects for rehabilitation from those who have already achieved maximal improvement

Discussion

Hollis S. Ingraham, M D , *Albany*—The study reported by Levin, Brightman, and Burtt is a noteworthy contribution to the knowledge of cerebral palsy and, additionally, is fraught with significance in certain other aspects The technic of the study itself merits comment

Here essentially is what may be called a field epidemiologic investigation of a noncommunicable chronic disease, utilizing not only Health Department personnel but also calling on the skills of other field workers It is an excellent example of the proper approach to the study of any type of disease prior to the initiation of any planning for control. It is only through combing a community carefully, ringing door bells, and interviewing families that one can hope to secure a true estimate of the prevalence or even of the full range of manifestations of most illnesses This has been demonstrated many times over in the field of the acute communicable diseases Only the illnesses which are obvious and manifest are known to the clinics and hospitals or even to the practitioner In practically all morbid states, there is a group of sufferers hidden from view, like the submerged volume of an iceberg

I am sure, in the future, that health departments will apply these and related technics increasingly to the study of chronic illness We are all aware of the fact that health departments are concerned more and more with the prevention or amelioration of chronic disease, and it is imperative that the technics which they have developed so successfully in the study and control of the acute communicable diseases should be utilized. It is to be noted that the original demand for health department participation in disease control studies often comes from special groups in the population and may, on occasion, be directly translated into legislative action

As a result of the survey itself, surmises as to prevalence can be replaced by estimates founded on an actual sample However, it is to be emphasized that even this large sample is not entirely adequate, and we are not in a position to say that the results of the survey can be applied without further checking to other areas It appears that at least in the survey area the prevalence rate of cerebral palsy is considerably higher than previously surmised, actually being at least double the estimate advanced by Phelps.

On listening to this report, one is again impressed with the complexity of cerebral palsy and with the necessity for giving much additional study and making haste slowly in one's efforts at amelioration

The high proportion of persons in this study found to be suffering from mental defects is particularly tragic and brings home the necessity for the careful screening of patients prior to the initiation of the very long, drawn-out, and exacting training required by so many of these patients

A study of the tables of prevalence by certain age groups calls attention to what would seem to be the excessively high mortality suffered by patients with cerebral palsy This is made apparent by the fact that, while the prevalence rate in the age group of five to nine years is approximately six per 1,000, it has dropped to considerably less than one per 1,000 in the age group centering around thirty, indicating that the mortality rate is many times that of the general population This fact would make one suspect that the excess mortality under five years of age might be even greater and hence the prevalence rates based on the five to nine age group would very seriously underestimate the actual frequency with which patients with cerebral palsy are born

This is on the assumption that the ratio of cerebral palsy individuals does not vary from year to year This assumption may be false It must be further assumed that the group surveyed in Schenectady was reasonably stable Since there has been no sharp increase in population in this area since 1910, this latter assumption is probably not too incorrect

I should like to compliment the authors again on this excellent study and suggest, in closing, that similar investigations are urgently needed in other areas of the country, so that the true situation may be more accurately assessed. Such studies would also demonstrate any trends in prevalence and might be so designed as to give further suggestions on the causation of cerebral palsy

INTERIM SESSION, AMERICAN MEDICAL ASSOCIATION,
DECEMBER 6 TO 9, 1949, WASHINGTON, D C.

VACCINATION AGAINST TUBERCULOSIS

HUGH M KINGHORN, M D , and MORRIS DWORSKI, B S ,* Saranac Lake, New York

(From the Saranac Laboratory)

IN PREVIOUS communications we gave the results of experiments with caseous vaccine, Koch's bacillen emulsion, and Calmette's B-C G [1-4] The caseous vaccine was obtained from the tuberculous lung or tuberculous gland of the cow

Our view was that if we used this caseous material as a vaccine, we might prevent the development of caseation and thus be able to vaccinate animals against subsequent inoculation of virulent living tubercle bacilli

Endeavors to obtain a vaccine for tuberculosis have been directed to the tubercle bacillus, either living or dead, or to substances in the tubercle bacillus We believe, however, that this is only part of a proper conception of the problem, and that as tuberculosis is a tissue disease, the necrotic caseous tissue might also contain substances for effective vaccination This caseous tissue contains not only tubercle bacilli but the substance that produced the caseation This substance was produced by the tubercle bacilli

Tuberculous material from the lungs or lymphatic glands of a bovine is often caseous throughout and can be easily removed as a thick pus suitable for purposes of the experiments

The Department of Agriculture and Markets of the State of New York supplied us with the necessary material, and we are deeply indebted to E T Faulder, J E Boyd, and J Woodward Claris for their interest and help

The preparation of our caseous vaccine and Koch's bacillen emulsion has been described [1] These vaccines are always heated on two successive days for one hour at a temperature between 58 to 60 C and tested for sterility by inoculation into guinea pigs Equal amounts by weight of each vaccine are used in the experiments Time and space will allow us to record only a few of our experiments We first tested our caseous vaccine against Robert Koch's bacillen emulsion, as we considered this to be the safest and best of the killed vaccines

EXPERIMENT 1

This experiment consisted of 30 rabbits, which were divided into three groups

Group A—Ten rabbits treated with Koch's bacillen emulsion made from virulent human tubercle bacilli

Group B—Ten rabbits treated with cow's tuberculous gland emulsion

Group C—Ten rabbits, controls, untreated

The weights of the rabbits in the three groups were about the same The details of the experiment have already been published [1]

TABLE 1 —DURATION OF LIFE

	Total Number of Days After Virulent Inoculation	Average Number of Days After Virulent Inoculation
Group A (koch s bacillen emulsion)—10 rabbits	2 091	209
Group B (caseous vaccine) —10 rabbits	2 348	234
Group C controls (untreated)—10 rabbits	1 661	166

The infecting dose of living virulent bovine tubercle bacilli, 25,000 organisms, overwhelmed the animals of all three groups, and all of them died of far advanced generalized tuberculosis

Group B (caseous vaccine) outlived the control by 687 days, an average of 68 days per rabbit

Group A (Koch's bacillen emulsion) outlived the controls by 430 days, an average of 43 days per rabbit

Group B (caseous vaccine) outlived Group A (bacillen emulsion) by 257 days, an average of 25 days per rabbit

EXPERIMENT 3

This experiment consisted of 60 guinea pigs which were divided into three groups

Group A—20 pigs treated with Koch's bacillen emulsion

Group B—20 pigs treated with caseous vaccine

TABLE 2 —PROTECTIVE VALUES

	No Tuberculosis	Minimal Tuberculosis	Moderately Advanced Tuberculosis	Far Advanced Tuberculosis
Group A—bacillen emulsion—18 pigs	3 (16 6%)	6 (33 3%)	4 (22 2%)	5 (27 7%)
Group B—caseous vaccine—20 pigs	15 (75%)	5 (25%)	0	0
Group C—controls unvaccinated—19 pigs	1 (5 2%)	4 (21%)	3 (15 7%)	11 (57 8%)

Terms

Minimal tuberculosis slight although positive evidence of tuberculosis in some of the lymphatic glands or doubtful disease in one or two organs.

Moderately advanced tuberculosis definite tuberculosis in some of the glands and in some organs but moderate in amount

Advanced tuberculosis extensive disease in the glands and organs.

* By invitation.

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Pathology and Clinical Pathology May 5 1949

TABLE 3 —EXTENT OF DISEASE (15 MONTHS AFTER FIRST VIRULENT INFECTION)

	No Tuberculosis	Minimal Tuberculosis	Advanced Tuberculosis
Group B—7 rabbits (Caseous vaccine)	6 (85 71%)	1 (14 28%)	0
Group D—8 rabbits (B C G vaccine)	6 (75%)	2 (25%)	0
Group C—9 rabbits (Unvaccinated controls)	1 (11%)	3 (33%)	5 (55½%)

Group C—20 pigs, controls, untreated

This experiment has already been published in detail.[1] Table 2 would seem to represent the protective values of caseous vaccine and bacillen emulsion. The infecting dose was 62,500 organisms of a virulent living human tubercle bacillus culture H_{60}.

In Group B (caseous vaccine), 75 per cent of the animals had no tuberculosis In the remaining 25 per cent there was a minimal tuberculosis No animal reached the moderately advanced and far advanced stages

In Group A (Koch's bacillen emulsion), 16 6 per cent had no tuberculosis In the remaining animals there was a minimal tuberculosis, 33 3 per cent, moderately advanced tuberculosis, 22 2 per cent, far advanced tuberculosis, 27 7 per cent. In this group 50 per cent of the animals reached the advanced stages

In Group C (unvaccinated controls) 5 2 per cent had no tuberculosis In the remaining animals of this group there was a minimal tuberculosis, 21 per cent, moderately advanced tuberculosis, 15 7 per cent, far advanced tuberculosis, 57 8 per cent In this group 73 5 per cent of the pigs reached the advanced stages

A definite immunity was obtained with caseous vaccine and Koch's bacillen emulsion over the unvaccinated controls

EXPERIMENT 6

This experiment was made to compare our caseous vaccine with Calmette's B C G[2] It was divided into three parts first, to determine what degree of immunity each vaccine produced with respect to extent of disease, second, to determine in which group the immunity persisted longest, and, third, to determine whether B C G vaccine would produce disease

The first part of the experiment lasted about fifteen months, that is, from the time the vaccinated animals and the controls received the virulent inoculation. The second part lasted one year, that is, from the time the animals of all three groups received their second virulent inoculation till the time the entire experiment was terminated

The experiment was based upon 58 rabbits divided into the following groups

Group B consisted of 15 rabbits which were immunized with four doses of caseous vaccine obtained from a cow's caseous gland at intervals of ten to eleven days A total of 126 mg was given Thirty-one days after the last vaccination, they were infected subcutaneously with about 5,000 living virulent bovine tubercle bacilli, B_I culture

Group C consisted of 15 rabbits, unvaccinated controls These rabbits were infected with 5,000 B_I culture on the same day as Group B

Group D consisted of 15 rabbits which were immunized with B C G vaccine, in four inoculations with a total dose of 16 mg, on the same day as Group B Thirty-one days after the last vaccination, they also were infected subcutaneously with about 5,000 living virulent bovine tubercle bacilli B_I culture

Group E consisted of nine rabbits which were injected with B C G vaccine at the same time as Group D to determine whether the vaccinating organisms would produce disease They received four inoculations at intervals of ten to eleven days, 16 mg in all.

PART I

The first part of the experiment ended fifteen months from the first virulent infection Duration of life was not significant, as a number of animals from each group died of pneumonia soon after virulent inoculation Two rabbits of Group B (caseous vaccine) died of pneumonia at 39 and 45 days, one rabbit of Group D (B C G vaccine) died of pneumonia at 26 days and showed no tuberculosis. These animals are excluded, as they lived too short a time after infection to be enumerated

Table 3 shows that caseous vaccine and B C G give definite protection

Group B (caseous vaccine) gave 85 71 per cent no tuberculosis, 14.28 per cent minimal tuberculosis, and no advanced tuberculosis

Group D (B C G vaccine) gave 75 per cent no tuberculosis, 25 per cent minimal tuberculosis, and no advanced tuberculosis

Group C (controls, unvaccinated) gave 11 per cent no tuberculosis 33 per cent minimal tuberculosis, 55½ per cent advanced tuberculosis

PART II

This was for the purpose of determining in which group, caseous vaccine or B C G, the immunity persisted longer

Six rabbits remained in Groups B (caseous vac-

TABLE 4 —DETERMINATION OF PERSISTENCE OF IMMUNITY

	No Tuberculosis	Minimal Tuberculosis	Advanced Tuberculosis
Group B—6 rabbits (Caseous vaccine)	1 (16 66%)	5 (83 33%)	0
Group D—6 rabbits (B C G vaccine)	3 (50%)	2 (33 33%)	1 (16 66%)
Group C—5 rabbits (Controls unvaccinated)	1 (20%)	0	4 (80%)

cine) and D (B C G), and five remained in Group C (controls) These three groups were reinfected with 25,000 bovine B_1 organisms in the left groin subcutaneously, 464 days after the first virulent infection

One year later the experiment was terminated by killing all the surviving animals The findings are shown in Table 4.

Group B (caseous vaccine) gave 16 66 per cent no tuberculosis, 83 33 per cent minimal tuberculosis, and no advanced tuberculosis

Group D (B C G vaccine) gave 50 per cent no tuberculosis, 33 33 per cent minimal tuberculosis, and 16 66 per cent advanced tuberculosis

Group C (controls, unvaccinated) gave 20 per cent no tuberculosis, no minimal tuberculosis, and 80 per cent advanced tuberculosis

The advanced tuberculosis in the lungs of the controls, Group C, consisted of many large caseous tubercles throughout the lungs Here again we see the protective value of caseous vaccine and B C G

Combining the two parts of this experiment we see that the extent of the disease in the rabbits in each group was as shown in Table 5

in the inguinal glands of two animals Inoculati of guinea pigs with material from these glands fail to produce tuberculosis Seven rabbits were e tirely free of infection The abscesses which d veloped in the groins of these two rabbits were d to the repeated large numbers of B C G organis which were injected B C G does not produ tuberculosis in rabbits

EXPERIMENT 7

In this experiment 85 guinea pigs of approximat the same weight were used, and were divided into t following groups

Group A—20 animals treated with sterilized po dered caseous gland emulsion—six subcutaneous jections into the groins at intervals of ten days o a period of 46 days with a total of 27 mg

Group B—20 animals treated with sterilized t not powdered caseous lung suspension—six sub taneous injections into the groins at intervals of t days over a period of 46 days with a total of 27 m

Group C—20 animals—treated with five inocu

TABLE 5 —TOTAL RESULTS

	No Tuberculosis	Minimal Tuberculosis	Advanced Tuberculosis
Group B—13 rabbits (Caseous vaccine)	7 (53 84%)	6 (46 15%)	0
Group D—14 rabbits (B C G)	9 (64 28%)	4 (28 57%)	1 (7 14%)
Group C—14 rabbits (Controls unvaccinated)	1 (7 14%)	3 (21 42%)	9 (64 28%)

Group B (caseous vaccine) gave 53 84 per cent no tuberculosis, 46 15 minimal tuberculosis, and no advanced tuberculosis

Group D (B C G vaccine) gave 64 28 per cent no tuberculosis, 28 57 per cent minimal tuberculosis, and 7 14 per cent advanced tuberculosis

Group C (controls, unvaccinated) gave 7 14 per cent no tuberculosis, 21 42 per cent minimal tuberculosis, and 64 28 per cent advanced tuberculosis

PART III

Group E of Experiment 6 was composed of nine rabbits immunized with B C G vaccine at the same time as Group D (B C G), to determine whether B C G would produce disease in rabbits They received four inoculations of B C G at intervals of ten to eleven days with a total of 16 mg They were not infected with living virulent tubercle bacilli

One rabbit died of an intestinal disorder 195 days after the first inoculation with B C G There was no evidence of tuberculosis anywhere in the animal Two of the rabbits died at 165 and 237 days after B C G inoculation They died as a result of fighting with two other rabbits and failed to show evidence of tuberculosis Another rabbit died of pneumonia at 427 days and showed no tuberculosis Another rabbit died of a generalized skin suppuration at 693 days with no tuberculosis Another animal died at 848 days of pneumonia with no tuberculosis. Three rabbits were killed to end the experiment at 892 days after first B C G infection They had no tuberculosis

Although the organs of every rabbit were examined both macroscopically and microscopically, the only evidence of a B C G infection was a focus

tions of B C G subcutaneously in groins at interv of ten days over a period of 39 days with a total 8 mg

Group D—20 animals—untreated controls

Group E—five animals treated with B C G alc —five inoculations subcutaneously in groins at int vals of ten days over a period of 39 days with total of 8 mg

The experiment was divided into three parts the purpose of determining the following (1) test these caseous vaccines and B C G against a ve large infecting dose of living virulent human tuber bacilli, (2) to see if a vaccine made from a co tuberculous gland was more potent than a vacci from a cow's tuberculous lung, and (3) to t whether B C G would infect guinea pigs

PART I

In this as in other similar experiments, it w found that when a very large infecting dose of li ing virulent tubercle bacilli was given to guinea pi previously vaccinated with Koch's bacillen emulsi or our caseous vaccine, no protection was obtaine In fact this large infecting dose overwhelmed the pr tection, and the vaccinated animals lived no long and sometimes shorter, than the unvaccinated co trols In contrast, the animals vaccinated wi B C G revealed an astonishing degree of protectio not only in their duration of life, but also in th amount of disease exhibited by them

PART II

With the powdered sterilized caseous gland emu sion, the 20 guinea pigs lived a total of 4,559 day with an average duration of 228 days after the viru

TABLE 6.—DURATION OF LIFE OF THE DIFFERENT GROUPS

	Duration of Life (Days)	Average Number of Days	Extent of Disease
Group A—20 Animals (Powdered caseous gland emulsion sterilized)	4 559	228	All had far advanced tuberculosis
Group B—20 Animals (Caseous lung suspension, not powdered but sterilized)	4 649	232	All had far advanced tuberculosis
Group C—13 Animals (B C G)	7 181	552	One pig had minimal tuberculosis two had moderately advanced tuberculosis ten had far advanced.
Group D—20 animals (Unvaccinated controls)	4 979	248	All had far advanced tuberculosis

lent inoculation All animals died from far advanced tuberculosis from 90 to 454 days (Table 6)

With the sterilized caseous lung suspension (not powdered), the 20 guinea pigs lived 4,649 days with an average of 232 days after the virulent inoculation. All animals died from far advanced tuberculosis from 91 to 404 days

With B C G vaccine, 13 guinea pigs lived 7,181 days, with an average of 552 days One pig had minimal tuberculosis, two had moderately advanced tuberculosis, ten had far advanced tuberculosis. These 13 pigs lived from 116 to 1,548 days after the virulent infection The first pig died of paralysis of the legs 116 days after virulent infection, the remaining 12 pigs died of tuberculosis Four pigs were killed for sampling at 230 days, and all had minimal tuberculosis, mostly in the lymph nodes

With the unvaccinated controls the 20 guinea pigs lived 4,979 days after the virulent inoculation with an average of 248 days All animals died of far advanced tuberculosis The first pig died at 136 days and the last at 416 days.

This experiment shows the enormous protection which B C G gives over caseous vaccine and controls when a very large infecting dose is used The powdered caseous gland emulsion and the caseous lung suspension (not powdered) gave about the same protection, and both vaccines lost their vaccinating properties by the overwhelming infection doses

Two hundred thirty days after receiving the virulent inoculation, four pigs of Group C (B C G) were killed for sampling All four animals had minimal tuberculosis Four animals of Group A (caseous gland emulsion) died about this time (from 214 to 242 days), and all had far advanced tuberculosis Four animals of Group B (caseous lung suspension) died from 214 to 251 days, and all had far advanced tuberculosis Four animals of Group D (unvaccinated controls) died from 219 to 231 days, and all had far advanced tuberculosis

Table 7 also shows the enormous protection which B C G produces over caseous vaccines and the controls.

Postmortem examinations were made on every guinea pig that died The organs of the animals of Groups A, B, and D showed the same amount of tuberculosis The organs of Group C (B C G) showed very much less disease, although when the disease was extensive, it was sufficient in amount to classify the animal as far advanced. In one of the B C G animals the disease was confined to the lymphatic glands

PART III

Group E of this experiment consisted of five guinea pigs inoculated with B C G at intervals of ten days from August 2, 1938, to September 10, 1938 A total of 8 mg was given

All the pigs which were vaccinated with B C G gave a positive tuberculin reaction These animals died from some extraneous cause or were killed from 388 to 2,097 days after receiving their first dose of B C G They were examined macroscopically and microscopically, and no organ tuberculosis was found The infection did not extend beyond the regional lymph glands It is thus seen that B C G does not infect guinea pigs

We believe that the B C G culture is safe to use on the human subject, and in our experience the culture has remained stable

E L Trudeau believed that there was considerable value in Robert Koch's and other tuberculins but became convinced that the living attenuated tubercle bacillus was necessary to give the greatest amount of immunity, Calmette believed also that it was necessary to have an attenuated living tubercle bacillus for this purpose, and he, therefore, developed his B C G

It is our belief also that the living attenuated tubercle bacillus is necessary to give decided immunity, and it is also our belief that the killed tubercle bacillus will not give such immunity as does the living attenuated germ. In the process of killing the germ, probably the most important substance of the germ is destroyed by heat.

Our caseous vaccine was prepared from a virulent killed bovine tubercle bacillus B C G was prepared from an attenuated living bovine bacillus We have shown how very greatly superior B C G is over our caseous vaccine with a large infecting dose, and we attribute this to the substance B C G is con-

TABLE 7.—EXTENT OF DISEASE AFTER APPROXIMATELY 230 DAYS

	Duration of Life	Extent of Disease
Group A—4 pigs (Caseous gland emulsion)	230 days approximately—died	Far advanced tuberculosis
Group B—4 pigs (Caseous lung suspension)	230 days approximately—died	Far advanced tuberculosis
Group C—4 pigs (B.C.G.)	230 days sacrificed	Minimal tuberculosis
Group D—4 pigs (Unvaccinated controls)	230 days approximately—died	Far advanced tuberculosis

TABLE 8.—Analysis of Bovine Lymph Glands—Normal and Caseous

Tissue	Alcohol Ether Soluble Substances: Water Content (% of Moist Weight)	Total Lipins (% of Dry Weight)	Cholesterol (% of Total Lipins)	Lecithin (% of Total Lipins)	Iodine (Number after Acid Precipitation)	Water Insoluble Residue from Alcohol Ether: Water Insoluble (% of Dry Weight)	Total Nitrogen (%)	Total Phosphorous (%)	Phosphoprotein (% of Protein)	Calcium (% of Ash)	Ash (% of Water Insoluble)
Normal bovine peribronchial and mesenteric glands	81 5	24 4	6 51	32 27	32 2	68 73	15 88	0 85	0 16	1 78	10 47
Caseous material from lymph glands semifluid mass no macroscopic evidence of calcification	75 16	19 49	26 58	12 10	51 2	78 22	10 64	5 07	2 04	32 68	41 13

stantly giving to the organism This most valuable substance is lacking in caseous vaccine When the infecting dose of living virulent tubercle bacilli was not large, our caseous vaccine seemed to be equal to B C G, but when there was a large infecting dose, our caseous vaccine guinea pigs showed no protection whatever and, in fact, lived for a shorter time than the controls The B C G pigs, however, showed very great immunity, not only in duration of life but in extent of disease

Use of Caseous Vaccine and Bacillen Emulsion on the Human

We have used both caseous vaccine and Koch's bacillen emulsion on a large number of patients suffering from pulmonary tuberculosis All had far advanced pulmonary phthisis and were not suitable for any other method of treatment While some excellent results were obtained on a few patients, many failed to show clinical improvement These killed vaccines will not cure tuberculosis when the disease is far advanced Yet we believe they have their place in treatment For instance, with patients that have relapsed, these vaccines are well worth using for possible protection against another relapse We have frequently seen fever of a moderate degree, between 99 and 100 F, disappear Intoxication is very decidedly lessened, and patients regain strength However, tubercle bacilli do not seem to disappear from the sputum Experimental evidence presented by us supports the efficiency of our caseous vaccine when the infecting dose of virulent tubercle bacilli is not too large It is possible that when the pulmonary tuberculosis in the human is not extensive, and when the general condition is good, caseous vaccine may be of decided benefit

Caldwell has analyzed normal and caseous bovine mesenteric and peribronchial lymph glands [5] His findings are given in Table 8 One of the outstanding differences between normal and caseous glands is the high cholesterol content of the caseous material Shope has used cholesterol as a therapeutic agent in experimental tuberculosis [6]

We wish to thank Dr Arthur Vorwald director of Trudeau Foundation, Saranac Lake for assisting us in the execution of this study

RESEARCHERS CONDEMN USE OF HORMONES AS BEAUTY TREATMENT

Treatment with hormones is not the answer to the problem of unwanted hair, a group of Duke University researchers found The researchers—Drs J Lamar Callaway, James T Wortham, and E C Hamblen, and A A Salmon, B S, of Durham, North Carolina, report their findings in the October issue of *Archives of Dermatology and Syphilology*

Women who come to doctors seeking such a treatment should realize that unneeded hormones not only may fail to relieve the condition but also may bring about significant alterations in ovarian function, the article indicates The only recommendation the doctor can give at present to women with unwanted hair not caused by specific disease, such as a tumor, is to stop overemphasizing the condition or use bleaching or safe methods of hair removal

TRENDS AFFECTING THE WELFARE OF RADIOLOGY

RAMSAY SPILLMAN, M D , New York City

I HAVE seen dissension in my own county society as to what constitutes the welfare of medicine, so I feel that I should define what I mean by the welfare of radiology By this I mean its maintenance at a level where it can live up to its responsibility in the grand pattern of medicine That means it must be able to attract young medical men as able as those who go into other branches

The long course of preparation for admission to medical schools today, the length of the curriculum itself, the basic internship, and the long period of preparation for the Boards should be a deterrent to any whose primary interest in medicine is financial But, by the same token, a candidate who has complied with all these exacting requirements should have earned at least a decent standard of living A specialty that cannot provide that and that cannot provide a professional prestige equal to that of any other branch will not attract as good candidates as it needs

I have seen five generations of radiologists and have known personally many individuals in each With very few exceptions, those of the first generation are dead, and dead before their time, of x-ray injuries From their experience we have learned how to survive

Those of the second generation are the elders of today I belong to the third generation, many of whom were once the assistants of the second We learned the craft by the preceptor system And now there is a fourth generation, and a fifth, that looks on me as a chronologic elder and shows me respect at the meetings and embarrasses me by calling me "sir"

The fourth generation has obtained its toehold, even though a precarious one I am a bit worried about the fifth generation They were in their residencies when they had to go into the armed forces They served, and served well, as did the fourth generation and some of the third But they never got a chance to try their wings on their own And what worries me is whether they ever will They are out of the service, and some of them have the diploma of the Board And where can they work? Gold or even silver leaves do not seem to be an inducement for them to stay in the Army or Navy in any numbers Some of them are working for the Veterans Administration, some of them are happy there and some otherwise

If life had gone on as it was going when I began in radiology in 1922, we of the third generation older now than the second generation were when they took us on as assistants, would be making places in our offices for more of these promising youngsters than we are Speaking for myself, I have not raised my fees in proportion to my increased costs, and, by the time I have paid my operating expenses and paid for my pro rate share of the kerosene to pour over the potatoes to destroy them, I don't have enough left to afford an assistant And, as my situation is not entirely unique, there are fewer assistantships for the fifth generation than there are candidates

If the applicant cannot get into an office that is a going concern, I don't see how he can expect, at present prices and present taxes, to equip an office and pay for it out of earnings, even if he begins as small as I did in 1928 No, not even if he shares it with several others So, unless the young radiologist has sources of income from his family, or from some other family, be it his wife's or some well-disposed relative or friend, an office of his own seems a very remote possibility

I know some men who are happy in their positions with the Veterans Administration I know others who are not, and who are either getting out or wishing they could get out And this despite the fact that they know they will have to be doing very, very well on the outside to make a net income equal to the salary they are leaving behind

By the simplest of arithmetic, then, the largest market existing for the talents of these aspirants is the hospitals The immediate past president of the State Society, Dr Leo F Simpson, has remarked, "The specialist, dependent as he is on the hospital to function, and lacking maneuverability to live under adverse economic conditions, could easily become the employe of the hospital trustees "[1] It is a very natural human desire, to be paid more if one works harder The straight salary hospital job is not the ideal situation A percentage of the gross receipts is more desirable But even a percentage of the gross receipts is subject to one consideration, namely More and more x-ray work in hospitals is being done on patients of the Associated Hospital Service or the Blue Cross, whichever name you prefer You know, and I know, that it is counter to the professed object of the Blue Cross

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Radiology May 6 1949

to put people in hospitals simply to get a diagnostic work-up, but you know and I know that it goes on Whether the radiologist is on a straight salary or on a percentage of the gross revenue of the department, this Blue Cross work brings him no revenue for his effort, because the Blue Cross pays the hospital a certain sum (I believe in some cases $16 a day), and to the best of my knowledge none of that money is allocated to the visible revenue of the x-ray department A hospital cannot maintain a patient and do a gastrointestinal examination on him, too, for any $16, and the result is that the hospital gives to the patient what the Blue Cross is not paying for, and then goes to the public with its hat in its hand, begging to make up its deficit On the morning of the day this was written, the newspapers carried a story that 423 voluntary hospitals were campaigning for eight million dollars to meet their operating expenses And a few weeks before that, a man very high in hospital councils in New York announced that the government was going to have to lend a hand in operating the voluntary hospitals He stated further that asking for government help was not the same as asking for government control I have my doubts about that The Blue Cross is not coming begging to the public You and I should have such a surplus as the Blue Cross has But some of that surplus is built from my time, and yours, and from the margin of safety that stands between me and leukemia, and between you and leukemia

Is this evidence that hospitals in general are operating on sound economic principles? When fewer and fewer opportunities outside of hospital practice are open to the rising generation of radiologists, can they be pardoned a bit of apprehension as to how firm the foundation? With a government committed to raising taxes even above present levels, for the stated purpose of reducing the money they will have left to buy things and thus ward off inflation, are people to have enough money left over, that is not spoken for, to make up the deficits of the volunteer hospitals?

During the recent war, a very likeable woman came into my office and identified herself as a lifetime social worker, engaged in a survey for the Bureau of Social Security to determine what the costs of x-ray examinations were in hospitals and in offices She was one of an earnest group of Federal social workers who were confident that the Wagner-Murray-Dingell Bill was about to cure all the ills of patients and doctors alike, medical and financial, and they wanted to know what it cost to do x-ray work, so they would know how much to let us charge I felt that if these people did get the upper hand over us we would be in a better position if they knew what the facts were I was in on the final conference, and so were several other New York men. It was a sincere study, based on a desire to ascertain fact. But I hope that I shall not be doing radiology when I have to use this or that number of films on a gastrointestinal study, even if the directive is based on the findings of this survey Some of this committee were impressed that the x ray machine is not used all day long continuously Well, even a radiologist likes to get out of the fluoroscopic room once in a while

Even though my own machine has intervals when the tube can cool off, I could not increase materially the volume of work my office turns out, even though the government should pay for it. And even if all the qualified younger radiologists were given facilities and subsidies, I do not believe that the proposed extension of benefits could be carried out on any such scale as the proponents of socialized medicine intend

Paradoxically enough, at the same time that enormously increased demand is made for x ray services, regardless of how paid for, the very improvement in diagnostic capacity of radiology is reducing the number of cases any given installation can turn out Two prominent workers, Swenson in Philadelphia and Coe in Washington, have shown recently how, by taking enough pains, they can show small polyps in the colon, many of which, although they look innocent enough, represent full-fledged but as yet nonmetastasized carcinomas * And when Coe brought out that it was sometimes necessary to examine these colons up to four times, I marvel at the lack of understanding in a fee schedule promulgated by a very large life insurance company, containing a line, "Abdomen (intestines, colon, rectum, kidney, etc) maximum payment, $10 " This may be a well-meant attempt to stave off state medicine by underwriting a part of the necessary fee for an x-ray examination, but I cannot be budged from the opinion that a $10 examination of the colon cannot reveal any but a gross average of pathology, speaking by and large, and that an insurance company is not rendering a public service by underwriting it I was told that if the premium were high enough to underwrite what certain radiologists feel is a competent standard of work, the cost would be prohibitive

The situation simply illustrates that the costs of satisfactory work cannot be pulled out of a hat *Dr Simpson states, "Compulsory health insurance involves compulsion, bureaucratic administration, and diminished quality of service to patients who need it due to the impossible demands of those who do not "*[2] You need look no

* Since this paper was read a group from Temple Texas won the gold medal of the American Medical Association at the 1949 meeting in Atlantic City with an exhibit which expands on this thesis —*R. S*

farther than England to see the truth of that statement There would be clearer thinking on how to get the maximum benefit from medicine if economists could grasp what any freshman in physics knows, that there is a law of conservation of energy and that neither wealth nor matter can be created out of nothing But, for many years past now, the more firmly an economist believed that it could, the higher he has been apt to be in the councils of the government

Two trends that affect radiology adversely today, as I see them, are first, passing the diagnostic buck to the x-ray at the very outset Among the internists who send work to me, there are some to whom it is very seldom I tell anything that they had not predicted in advance from a careful history and physical examination, plus a high degree of clinical intuition, which is just another name for using reasoning power The second trend is the ill-advised attempt to make x-ray available to everybody, in the face of Dr Simpson's well-worded warning of diminished quality of service to patients who need it due to the impossible demands of those who do not

Do I sound pessimistic? If so, let me leave you a final word of cheer, derived from a small book by a very wise ethnologist, Dr W M Flinders Petrie [3] He is probably the foremost student of the phenomenon that we call civilization He finds that a civilization, just like an individual, does not go on forever It is born, it grows, it matures, it becomes senile, and it dies He finds that we are in the eighth civilization of which history has a record, and that we are in the terminal stage Seven times before, the concentration of great wealth has ushered in the last stage before dissolution I find no evidence in his study that the destruction of wealth will restore a dying civilization In a normal culture, the amount of government bears a reasonable proportion to what else goes on I can see in the present expansion of governmental activities a definite parallel to a malignant tumor, and I firmly believe that the tumor will eventually kill its host

I think you will find food for thought in these few concluding words from Flinders Petrie

> At every invasion by a new people, which, as we have seen, is the necessary foundation of a new period of civilization, there must be strong personal rule The holding together of the invaders, the decisive subjection of the invaded, the strife of the fusion of peoples, all require an autocracy of greater or less scope This period lasts during four to six centuries
>
> The next stage is an oligarchy, when leadership is still essential, but the unity of the country can be maintained by law instead of autocracy This stage varies in length, in Greece and Rome it was about four centuries, in Medieval Europe about five or six centuries
>
> Then gradually the transformation to a democracy takes place, beginning about the great phase of literature in Greece, Rome, and modern Europe During this time—about four centuries—wealth—that is, the accumulated capital of facilities—continues to increase The accumulation of the facilities of life, or capital in every form, diminishes the need for striving There is so much the less worth striving for, there is so much more to enjoy without strife Hence, the easier life is rendered, the more easy is decay and degradation The maximum of wealth must inevitably lead to the downfall When democracy has attained full power, the majority without capital necessarily eat up the capital of the minority, and the civilization steadily decays, until the inferior population is swept away to make room for a fitter people

I call these considerations to your attention because I can recognize in the description of the scenery some landmarks on the road we are now traveling

HOPE FOR THE COCKTAIL IMBIBER

An interesting observation was presented by Dr Ross Golden at a recent Graduate Fortnight meeting of the New York Academy of Medicine, demonstrating the desirability of employing x-ray examinations of the gastrointestinal tract to aid in diagnosing allergy, amebiasis of the cecum, nutritional disorders, etc He quoted an example of a man greatly distressed because upper abdominal pains followed soon after taking a cocktail After preliminary x-ray examination showed the stomach functioning normally, he took a "barium scotch highball" Within a few minutes peristalsis ceased, and the antrum became spastic, suggesting the possibility of an allergic reaction to alcohol He was given a capsule containing antihistamine drugs and, if taken a half hour before imbibing the beverage, no discomfort resulted Thus, concludes Dr Golden, science can aid suffering humanity!

X-RAY STUDIES OF THE DISARTICULATED SKULL*

LEWIS E ETTER, M D , Pittsburgh, Pennsylvania

(*From the Western Psychiatric Institute and Clinic, University of Pittsburgh Medical Center, Pittsburgh*)

ROENTGENOGRAMS of the head present a confusing labyrinth of superimposed lines and shadows In order to separate these from one another and discover the exact details contributed by the various component bones, disarticulation of the dried skull was undertaken This dissection was accomplished by use of fine dental drills applied along the suture lines where necessary Then, by filming each component bone, at first separately in the various standard projections and next with it replaced in the skull, it became possible to correlate features found in the detailed analysis of the isolated bone with contiguous structures Now, if a film was made of the skull with the bone under study removed, the details of other related structures became more readily apparent It was possible then to see exactly how far a given line or anatomic structure extended and where it joined with a neighboring part In order to clear up any question regarding location of anatomic landmarks as shown on the films, small strips of lead were used to accentuate doubtful elements

It was found most instructive to deal only with the components of a single bone in relation to its neighbors at one time For example, the frontal bone enters into many of the standard projections of the skull If the whole dried skull was filmed it was difficult to say exactly where the frontal bone components ended and other bone structures commenced But if it was removed and films made of it separately, of the skull with it missing and then replaced, the exact anatomic features could be picked out and labeled By comparing the roentgenograms of the living skull in the same position it then was possible to label exactly the features of the frontal bone and not be confused with neighboring structures

Since the primary purpose of this study was to produce films for demonstration and classroom instruction, a matter of practical importance with reference to labeling presented itself All of the films of the bones prepared as above outlined had black opaque backgrounds surrounding the negative roentgen image If it was desired to preserve this appearance of the bone and not reverse the blacks and whites on the film it became necessary to get rid of the background The simple expedient of cutting out the roentgen image from the black film was developed, and the resulting silhouette glued to a sheet of cleared film gave ample room for lettering all the anatomic details Mounts prepared in this way were then placed between pieces of plexiglass and bound with tape, thus making a permanent teaching or exhibit collection Prints or projection slides can also be made from the original lettered and mounted silhouettes In addition to being used for the individual cranial bone study, this system is equally of use for mounting and labeling silhouettes of the whole dried skull or the roentgenograms of the living subject

A study of the sphenoid bone by the method described has been most illuminating As an example, the appearance of this keystone structure in the skull in the AP occipital, or Towne position is very instructive A photograph of the anterior inferior aspect of the disarticulated sphenoid is shown in Fig 1 Several of the anatomic landmarks are labeled, and particular attention is directed to the small triangular sphenomaxillary surface seen projecting downward as an inverted pyramid below the orbital surface of the greater wing This surface looks into the sphenomaxillary fossa, and its upper margin forms the posterior border of the inferior orbital or sphenomaxillary fissure It is of particular importance in the Towne projection because it is a prominent feature in the roentgenogram lying medially and below the mastoid

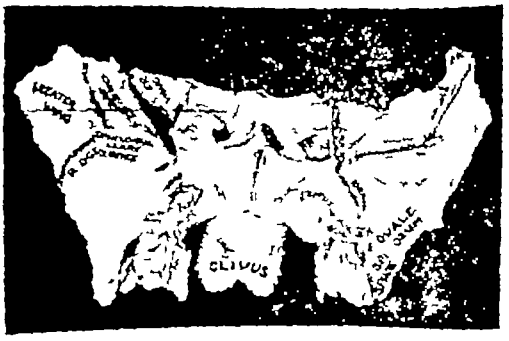

FIG 1 Photograph of the disarticulated sphenoid bone showing anterior-inferior aspect Note particularly the triangular sphenomaxillary surfaces

Presented, by invitation, at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo, Section on Radiology, May 6 1949

* A scientific exhibit New Method for Roentgen Anatomic Study of the Skull was shown in connection with this paper and given Honorable Mention in Scientific Research

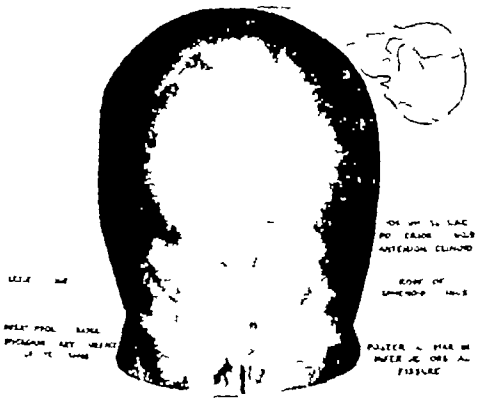

FIG 2 Occipital view—sphenoid components

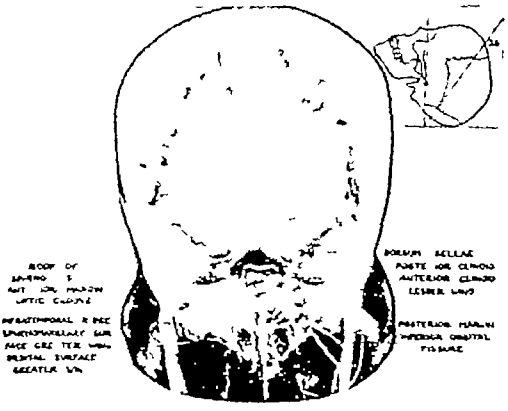

FIG 4 Sphenoid components—occipital view

tip for which it has been sometimes mistaken (Fig 2)

In Fig 3 a roentgenogram of the isolated sphenoid bone is seen, made with it in the same position it occupied in the skull when oriented for the AP 35 degrees toward the feet projection It will be seen that the sphenomaxillary surface is a prominent feature The relative positions of the anterior clinoid processes and the dorsum sellae are clearly delineated with lead markers as are also the orbital surfaces of the greater wings and the posterior margin of the inferior orbital fissure

If a film is then made of the dry skull with the sphenoid bone replaced, the exact details contributed by the sphenoid can be seen clearly by comparing the features with those demonstrated in the isolated bone (Fig 4) As described above, the sphenomaxillary surface is seen to be a prominent feature of this projection Its relation to the tip of the mastoid process and to the inferior orbital fissure is definitely proved To demonstrate the relation of the above structures to others in juxtaposition, a film of the skull with the sphenoid removed is seen in Fig 5 Here we can identify lines produced by the frontal, ethmoid, maxillary, mandible, occipital, and temporal bones, all having been previously identified by the same processes of analysis and synthesis Finally, it is a comparatively simple matter to study the view of the living skull in the same projection and pick out the features now certainly identified as belonging to the sphenoid

Summary

A method of x-ray analysis and integration of disarticulated cranial bones has been outlined Roentgenograms of individual bones were made in the same relative positions occupied in the skull in various standard projections Then

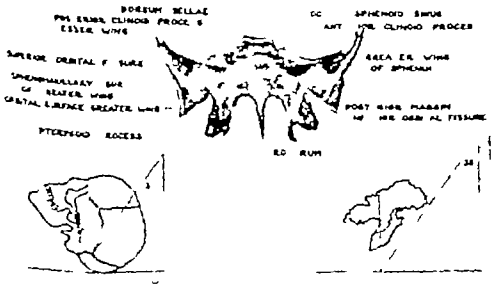

FIG 3 Sphenoid disarticulated—occipital view

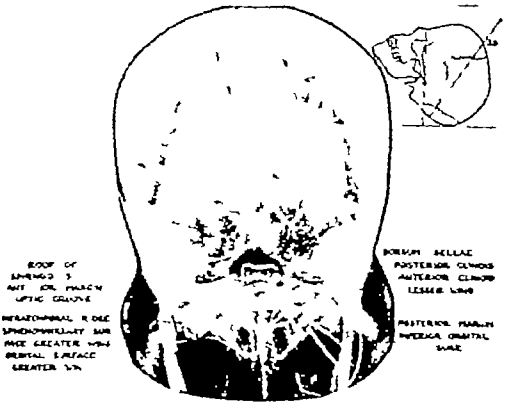

FIG 4 Sphenoid components—occipital view

tip for which it has been sometimes mistaken (Fig 2)

In Fig 3 a roentgenogram of the isolated sphenoid bone is seen, made with it in the same position it occupied in the skull when oriented for the AP 35 degrees toward the feet projection It will be seen that the sphenomaxillary surface is a prominent feature The relative positions of the anterior clinoid processes and the dorsum sellae are clearly delineated with lead markers as are also the orbital surfaces of the greater wings and the posterior margin of the inferior orbital fissure

If a film is then made of the dry skull with the sphenoid bone replaced, the exact details contributed by the sphenoid can be seen clearly by comparing the features with those demonstrated in the isolated bone (Fig 4) As described above, the sphenomaxillary surface is seen to be a prominent feature of this projection Its relation to the tip of the mastoid process and to the inferior orbital fissure is definitely proved To demonstrate the relation of the above structures to others in juxtaposition, a film of the skull with the sphenoid removed is seen in Fig 5 Here we can identify lines produced by the frontal, ethmoid, maxillary, mandible, occipital, and temporal bones, all having been previously identified by the same processes of analysis and synthesis Finally, it is a comparatively simple matter to study the view of the living skull in the same projection and pick out the features now certainly identified as belonging to the sphenoid

Summary

A method of x-ray analysis and integration of disarticulated cranial bones has been outlined Roentgenograms of individual bones were made in the same relative positions occupied in the skull in various standard projections Then

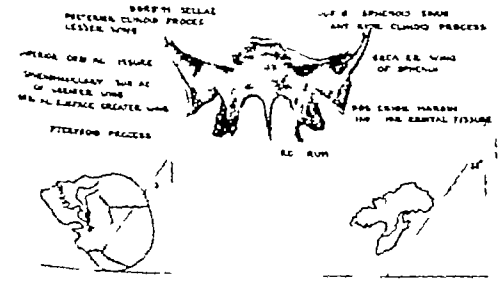

FIG 3. Sphenoid disarticulated—occipital view

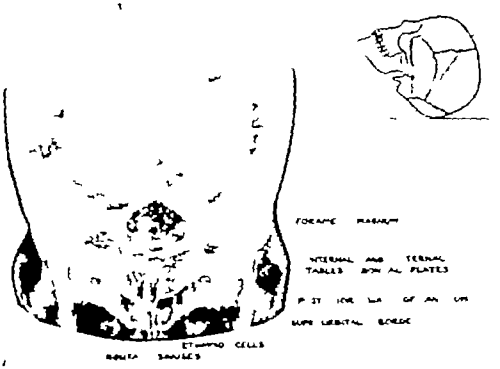

FIG 5 Occipital view—sphenoid removed.

roentgenograms were made of the skull with the bone in question removed Another exposure was made with the bone replaced In this way the exact features contributed to the roentgen image of the skull of the living subject by each bone were delineated and correlated

Discussion

George H Ramsey, M.D , *Rochester* —The roentgen examination of the skull and its contents has become an established procedure because of the direct visual evidence it adds to the clinical findings. If we are to give accurate interpretations, we must be familiar with the normal in the various projections

Dr Etter, in his radiologic dissection, has clearly and accurately labeled the lines and shadows contributed by each component of the skull. This method is both painstaking and time-consuming, but I am sure his effort is well repaid by the results

This research is being aided by a grant from the Sarah Mallon Scaife Foundation of Pittsburgh.

AMERICAN MEN MARRY

More American men are married, maintaining a home, and raising a family—and, what's more, apparently liking it—than ever before in the history of the country This is based upon a study of the American husband by the statisticians of the Metropolitan Life Insurance Company, who bring attention to the impressive fact that there are now about 35½ million married men in the United States, and that 34½ million of them are living with their wives.

Even the small proportion—approximately three per cent—living apart includes those men who are employed away from home or are temporarily absent for reasons other than marital discord, the statisticians note The otherwise happy situation is clouded somewhat by the fact that, because of the housing shortage, about 2½ million married couples are living with relatives or in other temporary quarters, such as transient hotels and lodging houses

Nearly one third of the husbands are under thirty-five years of age, and about one quarter are past fifty-five Of those at ages thirty-five to fifty four, 98 per cent are gainfully employed, or seeking employment, as a means of meeting their family responsibilities

Although the proportion of wives who work is greater than ever before, less than one fourth of all wives work outside the home, and these are mostly the younger ones who have been married only a short time

More than nine out of every ten young men in this country eventually marry All in all, American men look with great favor on traditional family life. They make a home, raise a family, provide for current needs, and save for their old age and for such contingencies as prolonged sickness and premature death.

A M A. SURVEYS BLOOD BANK RESOURCES

The American Medical Association is conducting a nation-wide survey of blood bank resources.

Under the direction of a special committee established by the A.M.A House of Delegates, the A.M A. Bureau of Medical Economic Research has just completed mailing questionnaires to more than 1,500 blood banks and 5,100 hospitals which have no blood banks The questionnaires are the first step in determining the capacity, equipment, personnel, inventory, general processing procedures, and arrangements for emergency cooperation among blood banks

The committee is headed by Dr Leonard W Larson of Bismarck, North Dakota Other members of the committee are Drs. William A. Coventry of Duluth, Minnesota, James Q Graves of Monroe, Louisiana, John W Green of Vallejo, California, Herbert P Ramsey of Washington, D C James R. Reuling of Bayside, New York, Deering G Smith of Nashua, New Hampshire, James Stevenson of Tulsa, Oklahoma, William D Stovall of Madison, Wisconsin, and Ernest B Howard of Chicago, assistant general manager of the A.M.A.

Organizations cooperating with the A.M A. in the survey are the American Association of Blood Banks, the American College of Surgeons, the American Hospital Association, the American Society of Clinical Pathologists, the Catholic Hospital Association, the College of American Pathologists, and the National Research Council.

THE PEPTIC ULCER PROBLEM

ALBERT F R ANDRESEN, M D , Brooklyn, New York

(From the Department of Clinical Medicine, Long Island College of Medicine, and the Long Island College Hospital)

ANYONE reading the literature on peptic ulcer must be amazed at the many different opinions expressed regarding etiology, pathogenesis, symptoms, and treatment of this common disease Patients who have made the rounds of internists, surgeons, psychiatrists, and cultists frequently ask me how there can be so much confusion in the ranks, and some of the more intelligent ones have expressed the opinion that the treatment of ulcer has become almost a "racket" Much of the confusion has been caused by ill-conceived and uncorrelated research by investigators unfamiliar with the clinical aspects of the disease The American Gastroenterological Association through its National Committee for the Study of Peptic Ulcer has made a careful study of the work that has been done and is attempting to promote a planned program of future study The United States Public Health Service has allotted $100,000 for subsidizing research in peptic ulcer under the guidance of the Committee, and it is to be expected that some constructive and authoritative reports will emanate from this source Meanwhile, an evaluation of the problem would seem to be in order

One fact in regard to the ulcer problem that stands out prominently is that no matter what type of treatment has been used, the reports show that ulcers have healed, as demonstrated by x ray and clinical findings before and after treatment Whether the patient has been treated by antacid, hormonal, or endocrine therapy, whether he has been fed through mouth or nose, into the stomach or duodenum or even through the veins or rectum, whether the foods have consisted mainly of carbohydrates, fats, proteins, or amino acids, whether psychotherapy, physiotherapy, or radiotherapy have been applied, and whether any one of the various operations, ranging from simple gastroenterostomy, pylorectomy, or gastrectomy to that "psychosomatic operation" of vagotomy, have been performed, the reported results have all been approximately the same The old familiar statistical studies, so notoriously inaccurate when applied to clinical reports in general, have been used to show the value of each of these methods of treatment Looking at the whole picture, any rational, unbiased person could come to only one conclusion—that uncomplicated ulcers must heal spontaneously and that the variation in healing time by different methods of treatment must be due to the fact that some treatments interfere with healing more than others

That uncomplicated ulcers heal spontaneously has been amply demonstrated in the past The most important point in the typical history of ulcer is so-called "chronicity and periodicity," by which is meant the occurrence, over a long period, of recurrent attacks of ulcer symptoms (hunger pain relieved by food) with often long intervals of entire freedom from symptoms, whether the patient has been treated or not During the intervals between typical attacks demonstrated to be due to ulcers, x-rays and even operations have disclosed either that no ulcer was demonstrable or, at times, that scars of healed ulcers were present Recurrent ulcers may be found at different points in stomach and duodenum in different attacks Lewis Gregory Cole, twenty-five years ago, at first by frequent serial roentgen studies and later by detailed pathologic research, demonstrated the rapid and complete healing of uncomplicated gastric ulcer [1] Later studies have shown that uncomplicated duodenal ulcers will also heal completely, although at times leaving deformities from scarring

Etiology and Pathology

Practically all treatments of ulcers have been based on the theory that ulcers are caused by erosion of the mucosa by acid gastric juice This theory has been based on the fact that excess secretion of hydrochloric acid has usually been found in the stomachs of patients with ulcer, ignoring the fact that some ulcers, especially those in the stomach, are found in the presence of an achlorhydria The fact that ulcers heal spontaneously or even where dilute hydrochloric acid has been given due to a mistake in diagnosis has been ignored In general, the increased acid secretion can be explained on the basis of irritation of the gastric mucosa caused by the presence of ulcer, and the spontaneous healing of the ulcer in the presence of the increased acidity could be attributed to the cleaning out of the base of the ulcer by the acid, promoting the healing process The increased acid secretion could thus be ex-

Presented at the 42nd Annual Meeting of the Fourth District Branch of the Medical Society of the State of New York, September 24, 1948.

plained as a protective reaction to the presence of the ulcer much more rationally than that it is a destructive agent

It is known that normal gastric mucosa is protected from digestion by gastric juice, so that it is necessary to presuppose damage or actual death of a localized area of mucosa before the juice could digest it out and produce an ulcer Cole, in his carefully checked pathologic researches, demonstrated conclusively that ulcers do not originate in the mucosa but, like boils and carbuncles, originate as necrotic areas in the deeper layers of the stomach wall, later breaking through the mucosa, the size of the resulting ulcers depending upon the depth and extent of the necrotic area [1] Large necrotic areas, such as those occurring along the lesser curvature of the stomach with its loose alveolar tissue, will produce the large ulcers seen there, whereas small ulcers are found in the prepyloric and duodenal regions When the necrotic areas are deep and occur in regions where the wall is thin and the lumen small, particularly in the duodenum, the breaking through may occur in both directions, through mucosa and serosa at the same time, producing perforation When a vessel happens to lie in the sloughed area, it may slough out or may be eroded by the gastric juice when it digests out the necrotic area, resulting in hemorrhage The extent of the induration occurring about an ulcer and the degree of accompanying peritoneal reaction is dependent upon the size and particularly upon the depth of the ulcer Stenosis resulting from cicatricial contractions after healing occurs mostly at the narrow pylorus and is much rarer than that resulting from perigastric and periduodenal adhesions caused by perforations, especially those so-called "slow perforations" into neighboring organs, principally the head of the pancreas, or such perforations covered by omentum

The reason for the occurrence of the necrotic areas constitutes the most important causative factor in the production of ulcer This fact has gradually come to be recognized, and many explanations have been advanced The fact that ulcers occur along the lesser curvature and the duodenum can be explained by the fact that there is an endartery circulation in this region That some ulcers occur as a result of obliteration of these endarteries as a result of arteriosclerosis, obliterating endarteritis, periarteritis nodosum, and embolism is undoubtedly true, but these are rare causes, as is syphilis That vasospasm resulting from psychic causes could proceed to actual death of tissue seems highly improbable, although the occurrence of ulcer following psychic trauma has been attributed to this cause That body habitus should play a part is incomprehensible and is belied by the fact that ulcer is seen proportionately as often in patients of asthenic as of sthenic habitus Some endocrine disturbances associated with vascular abnormalities could undoubtedly play a part in causing arterial spasm if not obliteration Allergy, which is known to cause sloughing areas elsewhere, as in skin, buccal, and rectal mucosa and conjunctiva, might conceivably be an important factor, but rarely are peptic ulcers directly attributable to allergy to ingested or inhaled substances

In 1912 and 1913 two research workers made contributions of great importance to the etiology of ulcer Rosenow demonstrated the connection between focal infection and ulcer previously suggested by Frank Billings [2] Turck produced typical gastric ulcers in dogs by the intravenous injection of simple extracts of homologous tissue, attributing the resulting necrotic areas in the stomach and elsewhere to absorption of a theoretic substance from dead tissue, which he called "cytost" [3] Later he called attention to the fact that "cytost" was undoubtedly present in small quantities in the necrotic tissue in so-called foci of infection and that the absorption could duplicate his findings after injection of "cytost" in dogs This was further emphasized when it was realized that Rosenow in his animal experiments injected mixtures of the infective material from foci of infection and not pure cultures of bacteria into his animal's veins, so that "cytost" was included The absorption of "cytost" would also explain the Curling ulcer following burns and the ulcers occurring after bad fractures or operations Whether "cytost" is the histamine-like substance which various workers are trying to implicate as the cause or whether the reaction in the mucosa is a so-called autoallergic phenomenon remains to be demonstrated

Thirty-five years of experience in the eradication of all foci of infection in my patients with ulcer has constantly emphasized to me the importance of focal infections in the etiology of ulcer I have never seen an ulcer occur in any case in which such foci could not be demonstrated as a cause, and recurrences, which might be postponed for an indefinite period by thorough eradication of foci, have practically always been found to be due to recurrence of old infections or the development of new ones That some patients tend to develop ulcers rather than other conditions known to be caused by focal infections would point to a constitutional tendency to the development of ulcer, which seems to be hereditary

Diagnosis

The history is the most important single factor in making a diagnosis Typical of peptic

ulcer is the history of "chronicity" and "periodicity," meaning the occurrence of attacks of "indigestion" lasting from a week to a few months with intervals between the attacks during which the patient can eat anything and have no symptoms whatever because then no ulcer is present The typical symptom-complex of hunger pains relieved by taking any kind of food or drink (or antacid) is usually present, being due to excessive gastric hunger contractions of the empty or nearly empty stomach occurring as a result of irritation from the ulcer This pain, usually in the epigastrium, may be reflected upward, downward, to either side or to the back, but at times, especially when the ulcer is complicated by disease in other parts of the gastrointestinal tract, the pain may be located in the gallbladder region, the back (with pancreatic irritation), the appendix region, or over the sigmoid In any case it will occur late after eating (one to three or more hours) and will be relieved by eating The time of occurrence of the hunger pain is independent of the location of the ulcer but is often directly due to the quantity of food ingested, occurring, as would be expected, earlier after small feedings, later after large meals

Another type of pain, due to pylorospasm in the case of an ulcer in close proximity to the pylorus, may occur immediately after or even during eating and is usually accompanied by retrostaltic symptoms such as nausea, belching (aerophagia), sour eructations, regurgitation, or even vomiting These retrostaltic symptoms may occur in any ulcer, regardless of location A third type of pain, due to peritoneal irritation, occasionally occurs in large lesser curvature ulcers when the crater becomes stretched with gastric contents, that is, immediately after filling the stomach, and will last until intragastric tension is relieved, usually one-half to one hour, being succeeded later by the hunger pains Peritoneal pain also occurs in deep duodenal ulcers which are impinging against peritoneum and is of course very severe if the peritoneal coat is perforated Persistent pain, little or not at all relieved by food, usually indicates a complication, such as a walled-off perforation and adhesions to neighboring organs or actual disease in these organs (pancreas, gallbladder, liver, omentum)

A little surface bleeding occurs in all ulcers, but gross hemorrhage is a complication to be discussed later

Roentgen diagnosis is valuable if performed by an expert To make a definite diagnosis of ulcer it is essential to identify a definite niche or crater filled with barium mixture surrounded by a defect due to inflammatory changes, edema, or induration This is only rarely possible on fluoroscopy, even large lesser curvature ulcers being easily overlooked Serial roentgenograms are absolutely necessary and must be taken in different positions, with and without compression, in order to bring out small ulcers Too often a diagnosis of ulcer is made only from the presence of spasm or because a deformity exists in stomach or duodenum At times, a crater not seen in the early films may be well visualized at one or two hours after the barium meal It is important to recognize the difference between the smooth crater of an uncomplicated ulcer and the deeper, often spreading crater or extravasation produced by a walled-off perforated ulcer, usually in the duodenum, which will often retain barium not only for six hours but for a long period of time Films taken at six hours will show whether an obstruction is present In any case a complete roentgen study, with films at twenty-four and forty-eight hours, a barium enema, and a cholecystography is advisable to identify complications which might have a bearing on successful treatment

Gastric analysis is of considerable value in many cases Fasting contents removed the morning after the usual rice and raisin "duration meal" taken at bedtime, if they contain visible rice and raisins, indicate a stenosis either in midstomach (hour-glass stomach), at the pylorus, or in the duodenum The quantity of overnight residue is somewhat of an index of the degree of obstruction, a large quantity with much liquid indicating a very small lumen The acidity may vary, being lower in gastric than in duodenal ulcer The microscopic findings include sprouting yeasts or sarcinae in the presence of free hydrochloric acid usually found in ulcer, as contrasted with lactic acid bacilli and free lactic acid when no free acid is present, as is often the case in carcinoma causing obstruction In high grade obstruction the overnight residue will often contain remnants of food eaten days before

Fractional gastric analysis will produce a curve of acidity which is not always characteristic In gastric ulcer the acidity may be high, approaching a free hydrochloric acid of 60 or 80 units, but it may also be low or even absent In duodenal ulcer the curve of free acidity usually rises rapidly to high figures, even to 90 or 100 or more, and tends to remain high, indicating the hypersecretion usually associated with this condition Absence of blood in the gastric contents is against the presence of an active ulcer, but its presence may be due to trauma in passing the tube If no blood is seen in the early removals but begins to be noticed toward the end of the examination, after one or one and one-half hours, coincident with regurgitation of bile into the stomach, it is

indicative of a source of bleeding in the duodenum and will confirm the presence of an active duodenal ulcer which may have been suspected only by x-ray examination The persistent finding of blood may also be of help in determining the presence of a postoperative marginal or jejunal ulcer

Gastroscopy, in expert hands, will show an ulcer if it comes within the limited area of the stomach which can be viewed by this method, but errors in diagnosis are frequent The new operating gastroscope designed by Benedict permits of biopsy, so that differentiation from carcinoma is possible in cases in which the ulcer can be reached

Stool examinations are of little value in ulcer Occult blood, found in so many stools even on a strict meat-free diet, may be due to slight trauma or bleeding anywhere from mouth to anus or in any of the tracts opening into the gastrointestinal tract Absence of blood may be an indication that no active ulceration is present and is of value in determining cessation of bleeding after massive hemorrhage

Other laboratory examinations, such as blood counts, serologic tests, and the various tests for possible specific diseases causing ulcer, will be of obvious advantage

The differential diagnosis between ulcer and cancer is important Duodenal carcinoma is very rare and is usually associated with biliary tract carcinoma, so that it is rarely confused with ulcer A gastric ulcer, on the other hand, must always be suspected of being a carcinoma with ulceration until proved benign, especially if the patient has no history of previous ulcers While an ulcer on the greater curvature is practically always malignant, the percentage of occurrence of carcinoma as compared with ulcer along the lesser curvature or on the posterior wall near the lesser curvature is not of great help in differentiation The fact that most carcinomas occur between the incisura and the pylorus does not mean that an ulcer seen elsewhere is not malignant The patient's safety demands a definite diagnosis The old teaching that gastric ulcer may become malignant was based on erroneous diagnosis, ulcers malignant from the start having been mistaken for simple ulcers As a matter of fact, gastric ulcers heal so rapidly that there is no time for malignant change to occur except in the scars resulting from healing, and this is very unusual The fact that simple ulcers heal so rapidly is the basis for making a re-examination of all gastric ulcers within three or four weeks after the finding of the ulcer when the ulcer crater may be found distinctly smaller or entirely absent and its surrounding induration diminished or gone, as contrasted with increasing and irregular infiltration in the case of malignancy and increase and often irregularity in the contours of the ulcer crater A few cases have been reported in which the carcinomatous crater was found to be smaller due to proliferation of the tumor tissue within the crater, but careful observation would show an irregularity of outline at this site and the increased surrounding infiltration It must be emphasized that inspection or even biopsy of the ulcer through a gastroscope, inspection and handling of it at operation, and even removal of the ulcer and its microscopic study may often not result in a definite diagnosis, and cytologic study of gastric contents is not absolutely diagnostic It is only by actually observing that an ulcer is healing or has healed, as shown by repeated x-ray studies, that a carcinoma can be definitely ruled out

Treatment

The treatment of peptic ulcer resolves itself into three principal indications the treatment of the simple uncomplicated ulcer, the treatment of complications, and the prevention of future ulcers

Prophylactic treatment is the most important As I mentioned before, ever since the relation between focal infection and ulcer was first demonstrated in 1913, I have carried out systematic and thorough eradication of all infective foci in the body, and my results have justified the really great effort involved in carrying out this program I have never observed the development of subsequent ulcers except in cases in which some new infection had developed, and subsequent care of these would then give excellent results Clinicians opposing removal of foci are invariably those who tried it but did not carry out a comprehensive program and, therefore, got no results My contention is that a clinician allowing obvious infections to remain in any patient who suffers from any chronic disease, whether it has been shown to be one due to focal infection or not, is not giving the patient adequate care, that is, he is treating a disease and not the patient Such neglect is getting to be too common

The presence of one small oral focus, like a retained root fragment in the jaw, may result in complete failure of this method of treatment, so that it is necessary, in the case of the mouth, to insist upon complete mouth x-rays and electric pulp-testing of all teeth, as well as direct observation Extraction of all nonvital or impacted teeth, removal of all retained fragments of teeth or fillings, and, in cases of pyorrhea, the removal of all remaining teeth, or at least of the teeth showing the greatest alveolar resorption, and thorough and frequent scaling of those allowed to remain X-rays after extractions must be insisted upon Such a program requires a degree of cooperation on the part of the dentist which is often difficult to obtain

Ears, nose, throat, and sinuses require a complete study and removal of even suspicious tonsils and necessary operative or other procedures for the eradication of infections in nose, sinuses, ears, and mastoid Chronic sinus infection offers an almost insuperable obstacle with ulcers recurring at any time when an exacerbation or new infection develops The ulcer symptoms usually begin at the end of symptoms of an acute upper respiratory episode I have found that the development of ulcer at such a time may be prevented by proper care of the acute infection, with particular attention to adequate drainage, to prevent absorption of the agent producing the ulcer

In the female, a very frequent cause of ulcer is the infected cervix, which may require anything from cauterization to extirpation Acute or chronic vaginal and uterine adnexal infections should of course be adequately cleaned up In the male, chronic infections in the prostate are a very common cause, but acute and chronic infections of any part of the genital tract should be eradicated Renal, ureteral, and bladder infections also must be treated

Although the three areas just mentioned constitute the most frequent sites of focal infection associated with the development of ulcer, others must not be neglected Rectal and colonic infections, pulmonary infections, bone infections, and even chronic skin infections must be eliminated Ulcers may also occur during any acute infectious disease

Treatment of the Uncomplicated Ulcer

Treatment of the uncomplicated ulcer is comparatively simple Realizing that such ulcers, no matter what their size or location, will heal spontaneously and completely in a matter of days or weeks, or, in the case of large lesser curvature ulcers, in a couple of months, all that is necessary is to provide conditions favorable to healing I tell patients that the ulcer is like the one occurring in the neck after a boil is opened, for which a salve is applied and held in place by a bandage In the stomach, instead of a salve, a diet like a salve should be used and kept in place by frequent replenishment The diet should be well-balanced, with possibly a slight excess of protein which long ago was shown to promote healing, and should consist of three meals per day with between-meal and nocturnal feedings at two or three-hour intervals while the patient is awake It has long been contended, and I agree with these observations, that animal protein does not agree as well with ulcer patients as egg, milk, cheese, and gelatin, so that I leave meat out of the diet for the first two or three months The reason for the irritation from meat is not definitely known, but perhaps the dead animal protein may contain a substance similar to the "cytost" of Turck. Forty years ago, when patients had ulcer recurrences, the eating of meat was blamed for them, and today I use a return to a normal meat diet as a clinical test of cure of an ulcer A return of an ulcer then indicates that some focus of infection has been overlooked The diet, which with slight modifications is the same as the one I adapted from von Leube's recommendation in my first paper on ulcer which I read forty years ago, is as follows [4]

ULCER DIET

Breakfast
- Milk one glass
- Cereal large dish, with sugar and milk or cream
- Egg one or two, soft boiled or poached
- Bread or toast with butter, one or two slices
- Juice of one orange, at end of meal

Midmorning
- Powdered gelatin, one heaping teaspoonful stirred into one-half glass of water followed by,
- Milk one glass

Luncheon
- Milk one glass
- Egg one soft boiled or poached, or cream cheese, one-half cake
- Baked or mashed potato or plain spaghetti
- Bread and butter, one or two slices
- Pudding, custard, gelatin, ice cream, or stewed fruit

Midafternoon
- Same as midmorning

Supper
- Same as breakfast or luncheon

At bedtime and at two and one-half-hour intervals in night if awake feedings as between meals

As this diet is somewhat deficient in vitamins and minerals, I usually prescribe these in capsule or tablet form Because of the deficient indigestible residue, a dose of one-half ounce of mineral oil may be given at bedtime There is no reason for interdicting salt In patients with marked gastric irritability a tablespoonful of vegetable oil may be taken just before meals Otherwise no medication is necessary or desirable I have not used alkalies or antacids or any other medication for over thirty years, and my patients do as well as any reported in the literature The feeding of predigested foods, formerly supplied in the form of peptonized milk and eggs and recently in the form of amino acids, is entirely unnecessary in a disease characterized almost invariably by excessive secretion of gastric juice Psychotherapy, in the way of explaining the simple requirements for healing, the uselessness of medication, and the undesirability of sedatives, will greatly aid in the rapid relief of

symptoms Most patients report complete cessation of pain within two or three days This diet is followed for from four to six weeks when vegetables and fruits are gradually added A full diet, with between meal feedings continued, is usually started at about three months, provided focal infections have been cleaned up in the interim X-ray check-up should show the ulcer healed

Surgical treatment is unnecessary in uncomplicated ulcer Failure to get relief by the diet outlined may be due to incorrect or insufficient diagnosis Other diseases with symptoms simulating ulcer or complicating ulcer, such as biliary tract disease, appendicitis, ileocolitis, diverticulitis, and even diseases outside the gastrointestinal tract, such as pelvic or genitourinary lesions, should be searched for and adequately treated Allergy to one or more of the foods in the diet may cause aggravation of symptoms I have seen immediate relief of symptoms previously aggravated by the ulcer diet when milk was eliminated from the diet Operative treatment should be confined to complications

The complications of ulcer requiring special care include hemorrhage, perforation, and stenosis Formerly, "carcinomatous degeneration" was included among the complications, but, as pointed out before, it is extremely rare, errors in the past having been due to mistaking a carcinomatous ulcer for a simple gastric ulcer In my experience patients with a history of previous ulcers who have later developed carcinoma have shown the carcinoma not to be located at the site of previously observed ulcers

Treatment of Hemorrhage

Hemorrhage is the most frequent complication of ulcer Slight bleeding, of course, occurs on the surface of all ulcers during the active stage As little as 30 cc of ingested blood will produce a black stool, and such a stool or a trace of bright blood in the vomitus without general symptoms of hemorrhage is of slight significance Real massive hemorrhage is usually manifested first by general symptoms such as sudden weakness, vertigo, palpitation, dyspnea, cold extremities, and sweating, the symptoms of shock. Frequently, such patients are treated for a "heart attack," especially when bright bloody vomitus and/or tarry stools are not noticed by patient or attendants I have even seen patients treated for "ptomaine poisoning" because they had arisen in the night and had vomited and passed a "diarrheal stool" in the dark, the subsequent anemia being attributed to the "poisoning" The real tarry stool is not merely black but of a sticky, tarry consistency, in severe cases mixed with liquid dark blood The vomitus may consist of bright blood or clots, depending on the length of time it has remained in the stomach. The blood count, before dilution of the blood by absorption of fluid from the tissues, will be the same as before the hemorrhage, dropping after twenty-four or forty-eight hours to its minimum if a single hemorrhage has occurred Continuous bleeding is most simply recognized by frequent recording of the blood pressure and pulse, a continuous fall in pressure and increase in pulse rate indicating continuous bleeding Prerenal azotemia with blood urea nitrogen up to 40 or 60 mm per 100 cc reaches its height in twenty-four or forty-eight hours and unless bleeding continues will gradually drop to normal in three or four days [5] It can, therefore, also be used as an indication of continued bleeding In a patient known to have had ulcers previously, a hemorrhage may be assumed to be due to ulcer, but it must be remembered that massive hemorrhage may be due to blood dyscrasias, ruptured esophageal varices, esophageal, gastric, or duodenal neoplasms, or even to severe gastritis Fortunately, the same treatment will be adequate for any of these causes, except that a ruptured varix might require cauterization

Nature's way of stopping hemorrhage from a bleeding vessel which is the usual cause of ulcer bleeding is by producing shock which enforces rest in a horizontal position, reduces blood pressure so as to prevent blowing out of the clot which forms at the site of bleeding, and increases the formation of blood coagulation factors It is important to aid nature in the maintenance of these conditions The patient should be at rest in bed, the blood pressure should not be raised suddenly by intravenous injections of any kind, and stimulants should be avoided While blood remains in the stomach, digestion of the clot is prevented by digestion of the blood, but when this has disappeared, the same effect can be secured by frequent feedings of soothing, liquid foods which combine readily with gastric juice and if possible act as coagulants Gelatin accomplishes this end The following is a copy of the routine treatment for hemorrhage used for many years on my service at the Long Island College Hospital and resulting in a mortality of about 2 per cent as compared with previous mortalities of 8 to 15 per cent by medical and 4 to 30 per cent by surgical treatments [6-9]

ROUTINE IN GASTRIC HEMORRHAGE

1 Order gastric hemorrhage diet
2 Treat shock by rest, warmth to extremities, and sedatives, if required
3 Quiet apprehension Reassure patient Do not isolate

4 Do not take a detailed admission history nor make a complete physical examination Do no more than rule out complications or bleeding from causes other than ulcer

5 Order blood coagulation tests coagulation and bleeding time, prothrombin time, vitamin K determination, and platelet count If coagulation is impaired, prescribe coagulants.

6 Type and match blood for transfusion No transfusion to be used in first ten days except for evidence of severe anovia Then try one or two transfusions of 150 to 220 cc of citrated blood If not successful, prepare for continuous drip transfusions to be used until bleeding stops or at least for thirty-six hours (may require 6 to 8 L of blood)

7 Chart blood pressure every two hours at first, blood urea nitrogen every two days at least

8 Test all stools for occult blood until this disappears

9 Start mineral oil, one-half ounce, every night after second night Retention oil enema on fourth night and thereafter as required

10 Do fractional gastric analysis on about the twelfth day in uncomplicated cases

11 Start x-rays on about the fourteenth day if bleeding has stopped

12 No gastroscopy until after x-ray

Contraindications

1 Ice Externally, increases shock Internally, stimulates gastric circulation

2 Parenteral fluids generally increase blood volume and pressure and cause more bleeding Small transfusions may be required in severe anovemia (See Routine)

3 Stimulants (digitalis, adrenalin, etc) tend to increase bleeding Only used in emergency

4 Alkalis stimulate secretion and irritate bleeding area

5 Excitement or worry increase shock, and reaction may increase bleeding

6 Examinations, manipulations, or treatments Only if absolutely necessary, especially in first few days

The formula for the gastric hemorrhage diet is as follows

Gelatin-Milk Feeding (Table I) Milk, cream, and dextrose are mixed together and kept in the refrigerator Gelatin, at the rate of 50 Gm per liter of the mixture or approximately 75 Gm. per day, kept in a paper cup at the bedside, is to be added at each feeding as follows A rounded teaspoonful is to be dissolved in one or two ounces of warmed milk mixture, and this is added to remaining cool mixture, making a cool, palatable drink. If the patient prefers it, the drink may be warmed A little flavoring (tea, vanilla, cocoa) may be added at time of feeding if desired

Routine For the first four days after the hemorrhage, feed 6 ounces of mixture every two hours, nothing else by mouth If asleep, the patient should not be disturbed for three or four hours

On the fourth, fifth, and sixth days add to three or four of the feedings one of the following one egg, soft boiled, poached, or raw, cereal, three ounces, custard, jello or ice cream, 3 ounces, and allow water in 3-ounce quantities between feedings

On the seventh and eighth days, add two of above foods to each feeding

On the ninth day, order ulcer diet

In patients who are allergic to milk or who object to it, a less satisfactory substitute is a mixture like the following (Table 2)

TABLE 1.—FORMULA FOR GELATIN-MILK FEEDING

Food	Amount	Carbohydrate	Protein	Fat	Calories
Gelatin	50 Gm.		45 Gm.		180
Dextrose	60 Gm.	60 Gm.			240
Cream (20 per cent)	100 cc	3 Gm.	3 Gm.	18 Gm	180
Milk	900 cc	36 Gm.	27 Gm.	27 Gm.	550
		99 Gm.	75 Gm.	45 Gm.	1 150 per L.

TABLE 2.—FORMULA FOR GELATIN-WATER FEEDINGS

Food	Amount	Carbohydrate	Protein	Calories
Gelatin	50 Gm.		45 Gm.	180
Dextrose	90 Gm.	90 Gm.		360
Juice of 3 oranges		30 Gm.		120
Water	to 1 000 cc			
		120 Gm.	45 Gm.	660 per L.

This is used the same way as the gelatin-milk mixture In milk allergy subsequent additions must consist only of milk-free foods

Vitamin C, 0 5 to 1 0 Gm per day, should be ordered with either routine diet

It will be seen from a study of the above routine that in the case of the gelatin-milk feedings, a patient taking nine or ten feedings per day will be consuming nearly 2,000 calories in twenty-four hours with about 100 Gm of protein In the case of the gelatin-water feedings only 1,000 calories will be taken, with only about 60 Gm of protein, represented by the gelatin alone, or more if the patient can take a protein mixture

In patients with stenosis complicating the hemorrhage, the treatment suggested for stenosis must be carried out In uncomplicated hemorrhage the usual studies are carried out after ten or twelve days, and complete treatment for ulcer is instituted

Surgical treatment for hemorrhage is not often recommended With operation of all hemorrhage cases at the onset of bleeding, the mortality in expert hands is two or three times as high as with medical care With operation after persistent, recurrent bleeding with the patient in severe shock, even under the most careful adjuvant treatment the mortality is so high that most surgeons refuse to operate In three patients ap-

parently moribund we have been able to save their lives by continuous drip transfusion over a period of thirty-six hours or more, using 6 to 8 L of blood

Treatment of Perforation

Perforation of ulcer may be of the acute or of the so-called "chronic" type Acute perforation due to sudden rupture of the ulcer through the peritoneal coat into the free peritoneal cavity usually occurs at the time the ulcer begins It may, therefore, occur suddenly without previous ulcer symptoms or with a history of previous attacks over years Where an ulcer has been shown to be present previously, the perforation usually can be demonstrated as due to another, new ulcer either at the edge of the previous one or some distance away The sudden terrific pain followed by shock and symptoms of peritonitis with shifting air demonstrable in the peritoneal cavity by roentgen examination or by diminished or absent liver dullness calls for immediate operation, although it must be emphasized that, to prevent too high a mortality, recovery from shock should be complete before the shock of operation is superimposed Simple closure of the perforation is the conservative procedure, leaving further care of the patient to the future

Chronic perforation is the term often used to describe the perforation which has been walled-off by the protective response of the omentum in covering up the site of the impending perforation or by adhesions to neighboring organs, most frequently the pancreas but also the gallbladder, liver, or colon producing an extravasation or fistula into these organs The onset of this perforation may cause very severe pain with signs of localized peritoneal irritation or acute pancreatitis or cholecystitis, which, however, does not increase or subsides gradually over an observation period of several hours, so that operation may be deferred

With the formation of firm adhesions spill is prevented, and an accessory pocket is produced This pocket, whose base is not stomach wall but the tissue of the neighboring organ, cannot heal up as in the case of an ordinary ulcer It may remain open for years, producing symptoms either continuous or intermittent, often brought on by exertion or other trauma, and sometimes accompanied by bleeding of the chronically inflamed tissues or by perforation at the edge of the pocket due to tearing away of adhesions Rarely, cicatricial contraction or granulations in the pocket may cause obliteration so that the pocket can no longer be seen roentgenographically with symptoms sometimes clearing up entirely or others persisting, or the contraction may cause stenosis

It is these perforated walled-off ulcers with accessory pockets which are the ones causing chronic persistent or frequently recurrent symptoms They are erroneously called "intractable ulcers"[10] They should be recognized at the time of a complete study, and the probable need for operation should be explained to the patient. After suitable preparation consisting of ulcer treatment as previously described, some suitable operative procedure is indicated

Treatment of Stenosis

Stenosis may occur as a result of inflammatory reaction, induration, and edema at the onset of an ulcer or as a result of cicatricial contraction following healing of an ulcer or adhesions or cicatricial contractions following perforated or almost perforated ulcers It is recognized by the cardinal symptoms of "delayed vomiting," the patient vomiting at long intervals all or nearly all of the food taken during the interval. Where only small amounts of food are being taken, the stomach may never become so overloaded as to cause vomiting, but the constant epigastric fullness and the belching and eructation of gas or sour material smelling of yeast may indicate the condition Rapid loss of weight and strength and increasing pallor are also noted The overnight residue already described under gastric analysis and the finding of a large atonic stomach with not only six but often twenty-four or even forty-eight hour gastric retention of the ingested opaque meal will clinch the diagnosis Often the ulcer will not be immediately demonstrable The purpose of treatment should be to give small amounts of concentrated liquid nourishment at frequent intervals to stimulate peristalsis and improve gastric tone, plus daily or twice daily aspiration of all gastric content to prevent overdistention and to act as index of improvement and parenteral administration of dextrose and amino acid solutions, fortified with vitamins, and minerals and any other medication which may be indicated Transfusions are also of help I use the same mixture of milk, cream, and glucose, with added gelatin as I use for hemorrhage but starting with four ounces of the mixture every two hours while awake and gradually increasing the quantity, adding raw eggs, protein preparations, and fruit juices and later cereals, puddings, and other foods, as indicated by improvement shown in diminishing returns on daily aspiration In cases where an inflammatory reaction with spasm was the cause of the stenosis, there is a gradual subsidence of the obstruction so that additions to the diet are readily taken The true organic stenosis may show some improvement, but more solid foods, even bread, will not pass the narrow point Repeated roentgenographic study after

ten days will determine the extent of improvement Some patients will show complete and permanent relief of the obstruction, others will require operation for relief In either case general ulcer treatment is indicated in addition

After operation, early feedings, following in detail the routine suggested for gastric hemorrhage, will usually result in an uncomplicated convalescence, and a subequent full course of ulcer treatment as suggested previously will give the best final results

TO A VIRUS

I

Twinkle, twinkle, little virus,
Do you find me so desirous
That you haunt me where I lie,
And you'll do so till I die?

II

First, you naughty little virus,
Like dots of red on white papyrus,
You daubed my skin with German measles
Not to mention coughs and sneezles

III

Then, my nonspecific virus,
You traipsed across my tired gyrus
And loosened full your endo-tox
The time you gave me chicken-pox.

IV

Then there came like a cadenza
Acute coryza with influenza
Tracheo-laryngo-pharyngitis
And equine encephalomyelitis.

V

Twinkle, twinkle, little virus
I wish I were a rose or iris
That has no lungs that consolidate
Then I'd snub you and go pollinate

MY ACHING BACK

I

Were I a victim of lechery
Or given to treachery
With bats in my turret
I'd much prefer it
To this nasty affliction
That defies prediction
I refer, to be precise and plain,
To this lower than low, low-back pain

II

Were I a case of megalomania
Or stowed away on the Mauretania
I'd sooner have it
(And be mighty avid)
Than this nasty disease
That none can appease
That has me on the torture rack
I mean that pain that's down the back

III

I've been a sufferer of colitis
I've seen gobs of myelitis
Not to mention
Marked retention
All of which I could endure
Acceptance that I'd ne'er adjure
If only you would break the strain
Of this awfully low, low-back-pain.
Or if none of these fine suggestions fit,
Could you please move it up or down a bit

PSYCHOSOMATIC ASPECTS OF REGIONAL ILEITIS

WALTER A STEWART, M D , New York City

(From the Departments of Psychiatry and Medicine, College of Physicians and Surgeons, Columbia University)

THIS paper reviews the proved cases of regional ileitis diagnosed over a nine-year period at the Presbyterian Hospital in New York City, with particular attention to the nature and frequency of psychiatric problems found

Review of Literature

The first systematic description of the disease was reported in 1923 by Crohn *et al* who compared the symptoms to those of ulcerative colitis [1] The cause remains unknown In the attempt to discover the causative agent, almost every possibility has been investigated [2]

There have been a number of papers dealing with the pathology of the disease Schepers suggested as one possibility that the disease was caused by a "neuropathic disturbance," a concept consistent with a psychogenic cause [3] A similar conclusion is offered by Morehead who writes, "Its high incidence in neurotic individuals suggests the possibility of vasospasm as the initiating factor "[4]

In a more recent review, Bockus points out that the etiology is unknown but states "I have encountered very few calm and phlegmatic persons with this disease Many of them were emotional, sensitive, rather excitable people At least four of 19 patients could be classified as severely psychoneurotic The most prominent personality traits were anxiety and emotional immaturity It has seemed to me that emotional immaturity is even more pronounced in patients with chronic regional enteritis than in those with chronic ulcerative colitis "[5] In a discussion following presentation of a paper by Garlock and Crohn, Dr H C Cave states that he had noticed nonspecific enteritis usually occurred among "high-strung, nervous persons not unlike that group of patients among whom duodenal ulcer frequently develops "[6] However, many writers fail to see the possibility that emotional factors may be a cause of structural changes, as suggested by Weiss and English [7 8]

Notwithstanding the suggestive comments made by Bockus, Schepers, and Morehead, there has been neither a systematic investigation of the personal history of patients with regional ileitis nor any study of the psychiatric factors which might play some role in the production of the disease This paper is a report of the investigation of these factors

Methods

The material dealt with in this paper was taken from the case records of the Presbyterian Hospital and included histories of patients in whom the diagnosis of regional ileitis was made during a nine-year period from 1940 through half of 1948 A total of 82 charts were examined In most of these records, the personal history, social service record, and the record of psychiatric examination contained sufficient material for the purpose of this paper However, a more intensive study of emotional factors was undertaken in those cases where the clinical diagnosis of regional ileitis was substantiated by subsequent operation and later histologic examination of the pathologic specimen

There was a total of 27 cases An attempt was made to interview these patients Of this group of 27, ten were seen on one or more occasions for the purposes of this study, 13 could not be found, and four were known to be dead

Table 1 presents an analysis of the total 82 cases in which the tentative diagnosis of regional ileitis had been made These cases are examined in terms of the correctness of the diagnosis and the presence of psychopathology

From Columns 1 and 2, it can be seen that in 27 cases proved to have regional ileitis by operation and by microscopic examination of the pathologic specimen, 20 were found to have significant psychopathology These cases are discussed in more detail later

In Columns 3 and 4 are ten cases in which both regional ileitis and ulcerative colitis were present either simultaneously or in succession Because it is now generally recognized that psychopathology plays some role in the genesis of ulcerative colitis, these cases were not included with those studied intensively Psychopathology was uniformly present in the entire group of ten

In Columns 5 and 6 are listed 20 cases in which the diagnosis of regional ileitis was made on the basis of clinical and laboratory studies Since the diagnosis was not confirmed by operation nor, therefore, by any study of pathologic tissue, no intensive study of these cases was made However, from the chart records alone it was apparent that psychopathology was present in 16 of the 20 cases

Finally, in Columns 7 and 8 are listed 25 cases in which the tentative impression of regional

TABLE 1.—Relationship of the Diagnosis of Regional Ileitis to the Presence of Psychopathology in 82 Cases Diagnosed at Presbyterian Hospital in New York City from 1940 to 1948

Year	Number of Patients	Correct Proved Diagnosis		Correct Diagnosis but Complicated by Ulcerative Colitis		Probably Correct Diagnosis		Proved Incorrect or Probably Incorrect Diagnosis	
		Number	Positive for Psychopathology	Number	Positive for Psychopathology	Number	Positive for Psychopathology	Number	Positive for Psychopathology
1940	15	5	3	4	4	3	3	3	0
1941	14	5	4	1	1	7	5	1	0
1942	11	3	2	1	1	3	2	4	1
1943	8	5	3	1	1	1	1	1	0
1944	7	3	3	0	0	1	1	3	0
1945	8	1	1	0	0	1	1	6	1
1946	8	1	1	3	3	1	0	3	1
1947	8	2	1	0	0	3	3	3	1
1948	3	2	2	0	0	0	0	1	0
Total	82	27	20	10	10	20	16	25	4

ileitis was later proved incorrect or most improbable In only four of the 25 cases was there evidence of psychopathology This group acts as a control series for the group in which the diagnosis of regional ileitis was proved correct

The table shows, by comparing the totals in Columns 1 with 2, 5 with 6, and 7 with 8, that, in those cases where the diagnosis of regional ileitis seemed likely, psychiatric factors were prominent (36 out of 47), whereas in those cases where the diagnosis of regional ileitis was improbable or incorrect, psychiatric factors were markedly less frequent (four out of 25)

A more intensive study of the 27 cases in which the diagnosis of regional ileitis was confirmed by operation was undertaken The equal distribution between the sexes, 14 men and 13 women, and the average age of onset of the disease at slightly below thirty years are in agreement with the reports of others [9 10]

Seventeen of the 27 cases were diagnosed preoperatively from x-ray films This confirms the opinion expressed by Brown and Donald that x-ray studies are the most important diagnostic aid [11] The x-ray findings in regional ileitis were those that have been described by Kantor [12]

Following study of the charts of these 27 cases, they were divided into three groups

1 Seven cases in which evidence of psychopathology was inadequate None was available for interview by the author

2 Three cases in which psychopathology was present and may have played some role in the disease process None was available for interview

3 Seventeen cases in which psychopathology was very prominent and probably played some role in the genesis of the disease process

In the seven patients comprising Group 1, there was little evidence in the history charts to suggest that emotional problems played a role in the onset or exacerbation of the disease This may, in part, be accounted for by the fact that none of these patients was available for interview The only personal history available had to be taken from the medical history presented in the hospital charts In five of the seven, there was no follow-up, and the period of time in which they were known to the hospital was eight months or less In the remaining two, the disease process was relieved following a single surgical intervention, and, therefore, there was no reason for inquiry into the personal history In spite of this, one patient gave a history of chronic constipation relieved by a regular nightly laxative He also had a son who had a "spastic colon" Another patient described herself as nervous and irritable, a third complained of nervousness and lack of self-confidence, a fourth described himself as nervous and high-strung, and a fifth complained of feeling discouraged and said she didn't want to live These comments were of course considered neither sufficient nor accurate enough evidence of emotional problems to justify including these patients in the group in which psychiatric factors appeared to play some causative role

There were three patients in Group 2 in whom there was sufficient evidence of emotional tension and strain so that it seemed likely that psychiatric factors played some role in the production of the disease None of these three patients was available for interview, the personal history obtained was limited to what was in the charts

One was a thirty-year-old, incredibly optimistic, dependent, obsessive-compulsive, "goody-goody" man who was unable to express aggression in any fashion Underneath his facade of cooperative agreeableness, there was evidence of considerable aggressive demands The second patient was a hard-working, self-reliant accountant who described himself as having always been of nervous temperament and a poor sleeper His tense, driving temperament, combined with his inability to accept help, which was in conflict with his obvious dependent needs, suggested that psychiatric factors may have played some role in his illness The third patient in this group, a seventeen-year-old Jewish girl, was described as

tense, nervous, demanding, uncooperative, and irritable It was felt that her mental status was such that even medical treatment was impossible, and she later died

The remaining 17 cases (Group 3) gave definite evidence in the history that the onset and later exacerbations of the disease were correlated with emotional problems Of this group, seven were interviewed for the purposes of this paper, eight were seen by a psychiatric consultant in the course of their hospital stay, and only two were not at some time seen by a psychiatrist Seven of the 17 were treated psychiatrically, and one other was committed to a mental institution where she died

A summary of one of the case histories, with protocols of three others, are included here as examples

Case Reports

Case 1 —R F was a thirty-three-year-old Negro subway porter His chief complaints were symptoms suggestive of intestinal obstruction He gave a long history of borborygmi and constipation When interviewed, he appeared to be a soft-spoken, receptive, dependent, and ingratiating person

He described his mother as a hard-working, well-meaning person She was first married to an actor who left her $10,000 when he died She next married the patient's father, who is described as a professional confidence man, a gambler, bootlegger, and dealer in narcotics

The patient recalls frequent police raids on his home during his childhood His father would generally get away, but his mother would be locked up His father deserted the family when the patient was seven His mother then worked in a laundry to support the patient and his siblings, two sets of twins

The patient began work when nine years old, washing cars Shortly after this, his mother remarried for the third time, "because things were so tough" This marriage is described as the worst her third husband had served ten years in jail and had committed a number of murders He was abusive to her and to the patient The patient remembers with anger and resentment how frustrated he was because he was too small to fight back Later the third husband again went to jail When he got out, the patient was twenty-one years old and refused to let him stay in the house He had to "run him out with a knife"

The patient married at sixteen His wife was seven months pregnant at the time of marriage She had a bad reputation and had "never tried to make anything of herself" He married her because he was afraid he would be sent to reform school if he didn't They had frequent fights, and she threatened him with a knife on several occasions. She was described as insanely jealous but frequently unfaithful He wanted a divorce which she would not give him. He felt frustrated because he was unable to force a decision His children were insecure, fearful, and cried frequently

He left his wife for four years (1930 to 1934) and lived with his mother and his two older children. During this time he met his present fiancée His wife finally brought court action against him for increased support which he felt he could not provide Therefore, he returned to her, telling his girl friend he was going to try again to make a success of his marriage A few months afterwards, his stepfather returned to live with his mother The patient cried when he saw her take him back However, the stepfather soon began fighting, drinking, and gambling again and was forced to leave after three months

After this, the patient was the main support of his mother as well as his wife and children but continued to see his girl friend He was working hard trying to get ahead in the Civil Service, taking evening courses and working as a subway porter He tried a job as street car conductor for a month but found it too strenuous and said, "It almost caused me a nervous breakdown" His youngest son had developed ulcerative colitis and required tutoring at home

Because the patient had the burden of his father and then his stepfather and the constant burden of his mother, wife, and children, he was unable to realize his highly ambitious goals to better himself and felt deeply frustrated His wife had found out about his girl friend and had tried to "cut her with a knife" He was also in debt It was in this setting that his illness finally became acute with obstruction and required his hospitalization

While the patient was in the hospital, the social service agency arranged for relief support of his mother Following discharge from the hospital, the patient drew his pension money which he used for a divorce This was the first time he had had enough money to make this step His mother died at this time, and he began living with his fiancée whom he describes as "a lovely girl who is kind and generous and gives me moral and financial support"

He has since been promoted in his job so that he has a permanent position as a subway guard At present he is moved from one station to another each day and works either on the platform or in the change booth He has, on a number of occasions, been assigned to the busiest stations When he reports for work, he feels tense and insecure, and these emotions affect his gastrointestinal tract He states, "The necessity of tackling the job makes me feel insecure and goes to my stomach and causes me diarrhea Anything that makes trouble for me makes me feel insecure, makes me feel rebellious When this clears up I feel O K When I feel that I'm master of the job, I stop being tense I like a conservative life, not an exciting one I get rattled when people try to hurry me and that makes me burn up inside" He has two bowel movements per day on a quiet day, but when he gets excited it goes up to five or six a day

In spite of his desire for a conservative life, whenever he reaches some reasonable expectation of emotional or financial security, he undertakes additional

responsibility which jeopardizes his position This results from the conflict of his dependency needs and his ambitious goals

Case 2—J K. was a forty-six-year-old Jewish printer He described his mother as a nagging, dominating person, whom he never felt free to criticize. He appeared to be a dependent, passive, and immature person whose ambitions lay well beyond his ability

His illness began at a time when he felt very guilty over a protracted affair he was having with a married woman It became worse when he found she was also intimate with another man However, he continued his relationship with her because he worked for her grandfather When this situation ended, his symptoms subsided, although he noticed he had diarrhea when he became emotionally upset

His most recent attack followed an argument with a tough neighbor, in which he was told to "shut up or fight." He shut up but couldn't get over the humiliation of the affair He was unable to sleep, lost his appetitite, and felt lonely and depressed

He described himself as easily upset, a shy, self-conscious worrier who "boils inwardly" and broods when facing a situation calling for aggressive action

Case 3—H W was a forty-year-old Jewish deputy collector of internal revenue He appeared to be an insecure, tense, emotionally labile person The diagnosis of regional ileitis and anxiety state was made At the time of hospitalization he had frequent suicidal preoccupations and was demanding and resentful

His life history revealed that he was orphaned at the age of eleven months and subsequently developed a "fight-at-the-drop-of-a-hat" philosophy In 1935, following his separation from his wife because of numerous quarrels, his son contracted a severe case of poliomyelitis The patient was extremely anxious, worried, and depressed during this period, and it was then he first developed his symptoms The attack subsided following surgery and his reunion with his family He was on his good behavior and says, "Instead of fighting back when someone tread on my tail, I was quiet, but I felt it in my guts"

Case 4—L L was a twelve-year-old Jewish boy His mother was a dominating, possessive person The father was described as demanding and irritable. As a child, the patient was both a behavior problem and a feeding problem He was toilet-trained early In spite of the obvious overt hostility between the patient and mother, he described himself as dependent on her and constantly in need of her presence

Later, when the patient voluntarily expressed the idea that worry and dissatisfaction had a marked effect on his symptoms, he recalled that at the time of the onset of his illness, he had had a premonition that his mother was going to die He also had the idea that he would die too, and there "would be no world for anybody" It was noted in his chart that improvement in his long illness dated from the first day he got his job After considerable pressure, his mother was persuaded to let him go to Arizona alone He later wrote from there that he was physically well and mentally very happy

Comment

In this type of study, no decisive relationship of emotional problems to a somatic disease such as regional ileitis can be shown At best, the study may serve as a stimulus to further inquiry However, the material presented does strongly suggest some type of interrelationship The first piece of evidence for this is the high correlation of both emotional problems and regional ileitis in those patients with proved diagnosis when compared with a control group without regional ileitis A second piece of substantiating evidence is the fact that exacerbations of the disease are found to coincide in time with some disturbance in the emotional life of the patient In addition, there is some suggestion that the severity of the disease and the prognosis are related to the severity and chronicity of emotional disturbances

If regional ileitis is conceived of as a psychosomatic disease, comparable in many ways to peptic ulcer and ulcerative colitis, it should be possible to treat selected cases in the same way that selected ulcer and colitis cases have been treated, that is, by vagectomy [13,14] In this series only one patient has been treated by vagectomy It is too early to make any evaluation of the result

A final piece of evidence favoring the concept that emotional factors are important in regional ileitis comes from even a superficial examination of the psychodynamics of the 17 patients comprising Group 3, who all display certain similarities in their patterns of psychologic adaptation In all of them, overt fear and repressed rage were present as part of a dependency pattern of adaptation produced as a defense against a threat to their security

It is not suggested that the dependency pattern of adaptation associated with overt fear and repressed rage is unique in regional ileitis, since it is observable in most patients who have an illness in which emotional factors contribute to the genesis of the somatic disease The additional constitutional, hereditary, or experiential factors which must also exist and which determine the choice of the end organ are as yet unknown

The evidence cited above furnishes the present basis for the psychosomatic concept of regional ileitis This concept permits the following formulation of the known facts It is felt that emotional factors start the series of events in some cases In persons predisposed by constitutional or hereditary factors or early childhood experiences, the emotional disturbance produces, via the autonomic nervous system, a disorder of gastrointestinal physiology, characterized by hypermotility, spasm, and hypersecretion These changes produce an inflammatory reaction with lymph-

edema and finally necrosis and ulceration in the mucosal crypts This is an early, or acute, stage from which some patients recover spontaneously and at which time in other cases psychotherapy or vagectomy might be therapeutic

If, however, the precipitating factors continue, the illness gradually progresses with further necrosis, continuous diarrhea, further inflammation, secondary infection, pain, and anemia The progression of the illness ends in irreversible scarring and hardening of the small intestine and finally obstruction Because the structural damage in the late stages of the illness is irreversible and because the local gastrointestinal lesions become autonomous, treatment requires surgical intervention, either a short-circuiting operation or resection

Summary

The charts of 82 cases of regional ileitis accumulated over a nine-year period at the Presbyterian Hospital in New York City were examined for the presence or absence of psychiatric factors In 25 cases the diagnosis of regional ileitis was disproved or seemed unlikely Of these, only three seemed to have any emotional problems In ten cases, ulcerative colitis coexisted, and in all ten emotional factors were present

In the remaining 47 cases, in which the diagnosis of regional ileitis seemed probable, emotional problems were present in 36 In 27 of these 47 cases, the diagnosis of regional ileitis was proved at operation and by examination of the pathologic specimen

The histories of these 27 proved cases of regional ileitis were studied in detail In 20 patients, sufficient evidence was obtained to suggest that emotional factors play a considerable role in the production and progress of the disease In the remaining seven cases, no information was available as to the role of emotional factors A formulation of the disease from a psychosomatic point of view is presented

SCIENTIFIC EXHIBITS
1950
ANNUAL MEETING

Applications for space for the scientific exhibits should be made directly to the Chairman of the Subcommittee on Scientific Exhibits of the Convention Committee

Dr J G Fred Hiss
505 State Tower Building
Syracuse 2, New York

The Annual Meeting will be held May 8 to 12, 1950, at the Hotel Statler in New York City

No applications can be considered after January 1, 1950

There will be two groups of awards

Awards in Group I are made for exhibits of individual investigation, which are judged on the basis of originality and excellence of presentation

Awards in Group II are made for exhibits which do not exemplify purely experimental studies and which are judged on the basis of excellence of presentation and correlation of facts.

W P ANDERTON, M.D , *Secretary*

THE MANAGEMENT OF EAR PROBLEMS IN CHILDREN

MARVIN F JONES, M D , New York City

(From the Department of Otolaryngology, Manhattan Eye, Ear and Throat Hospital)

THE solution of the problems of deafness or impaired hearing in the adult may be found in the child Aside from the fenestration operation there is little to offer the adult patient to restore useful hearing With the exception of the comparatively small percentage of otosclerosis patients among people with impaired hearing, nothing except a hearing device will restore adult loss of hearing to a useful hearing level This statement does not hold true for the child A child's impaired hearing may be improved, cured, or prevented

There are many reasons why hearing difficulties of children have been overlooked or ignored The youthful patient is always more of a diagnostic problem than the adult and perhaps more of a challenge to the ability and tolerance of the otologist Parents sometimes complicate the problem for both the child and the otologist A knowledge of child psychology, parent psychology, a complete understanding of otolaryngology in children, plus endless patience must be at the command of any doctor who is to work in the only field where prevention or cure of deafness is now possible Diplomacy, in its finer sense, must control all the actions of the doctor

When a nice little child cooperates beautifully during the routine examination and the beaming parents are justifiably proud of the youngster's behavior, it takes real courage to follow through and complete a nasopharyngoscopic examination But, unfortunately, such an examination may be the most important part, since it is the most satisfactory and perhaps the only satisfactory way to examine a child's nasopharynx. The procedure usually gives the most valuable information obtainable Too few otologists have taken advantage of this instrument in routine examinations The usual method employed is to insert a finger between the child's carefully guarded teeth into the nasopharynx. This is an informative procedure and sometimes necessary, but it is also a strain on the heretofore friendly patient-doctor relationship Again I say the proper use of the nasopharyngoscope is the only method which enables an examining doctor to make a satisfactory examination of a child's nasopharynx When the child is not cooperative, such an examination is practically impossible and may be dangerous The use of a transient general anesthesia is justified We must be very sure of our grounds, however, before we subject our small patient to the slight additional risk from an anesthetic

Something has happened in the past several years to reduce the incidence of acute and chronic otitic infections in children This decrease started before antibiotics and sulfa drugs came into use If anyone accepts the statement that such infections diminished before these new medications were used, the individual must ask himself why In response to the question, some possibilities come to mind After careful consideration, some of the following causes may be classed as probable

Wholesale removal of tonsils and adenoids has been condemned, and perhaps with justice Those of us who have legitimately removed these tissues have felt like hanging our heads in shame because of confrère and public onslaught I doubt if anyone will question the fact that overenthusiasm in the past has placed a certain stigma on a useful and necessary surgical operation ; We have damned each other and been damned by others for removal of tonsils and adenoids, but I have reached the conclusion that this almost routine procedure of not so many years ago has had a beneficial effect on the health of the patients thus treated Complications of upper respiratory infections have been less

In recent years, the otolaryngologists have been condemned because of their sometimes overenthusiastic tonsil and adenoid surgery, but, when the final estimate is given, I believe this surgery can be credited for a diminution in all types of ear infections, sinus infection, and the malnutrition in children not caused by insufficient and poor food In a child with impaired hearing, the tonsils and adenoids should be thoroughly removed by surgery This statement is not in agreement with other authorities, but I believe it will stand the test of time

The use of radium for the removal of pharyngeal lymphoid tissue has had a thorough trial under Crowe at Johns Hopkins The subject is one of great controversy This work has been imaginative, meticulously done, and laboriously followed up No such carefully recorded observations have been done in similar numbers of patients in order to determine hearing results obtained by the usual methods Such work would

Presented at the annual meeting of the Georgia Society of Ophthalmology and Otolaryngology Savannah, Georgia, March 4 1949

furnish a comparison of the results obtained by the use of radium and other methods, both experimental and standard

Having had unfortunate experiences with radium in its earlier application, I have been perhaps unduly concerned about the late effects of such radiation The recent reports have not tended to allay my apprehensions We must all decide what methods we employ on the basis of the results we ourselves are able to obtain The results we have attained at the Conservation of Hearing Clinic of Manhattan Eye, Ear, and Throat Hospital have not equaled the enthusiastic claims of others Perhaps the use of radium has had an unexpected good result in that the use of the nasopharyngoscope has become more popular It is assumed that no otologist would presume to apply a radium applicator to the nasopharynx before an examination with the nasopharyngoscope in order to determine whether or not the pathology exists which radium is supposed to correct There is also the danger of overenthusiasm affecting our scientific eyesight I have not seen the marked changes in the nasopharynx in the comparatively few cases I have examined who were treated with radium I have removed tonsils and adenoids which have been subjected to the radium treatment, and the radiation failed in its purpose However, in order to determine whether adenoid tissue is present, one must use the nasopharyngoscope intelligently and observe the results obtained at operation Such an examination, with proper records, will prove whether the adenoid growth appearing at a later date is a regrowth or a remnant It may also prove that the cause of a regrowth is a recurrent sinusitis It may also prove that the underlying factor of the recurrent sinusitis is an allergy If this is a byproduct of the investigation of radiation, the byproduct may have more far-reaching, beneficial effects than the main project

For some years the optional operations have been scheduled at a time when the upper respiratory infections were at a minimum This category includes tonsillectomy and adenoidectomy Our most propitious time seemed to be during the summer months Then came some rather dramatic pronouncements, which were properly publicized by interested agencies, regarding the increased incidence of poliomyelitis following tonsillectomy It seems that again statistics were made to paint a modernistic picture with distorted values The judgment was that not only the winter months but also the summer months were on the forbidden list for tonsillectomies The summer being the time of prevalence for polio, it was claimed to be advisable to discontinue tonsil surgery during the summer This leaves no time for tonsil surgery which is acceptable However, tonsil surgery must still be done Subsequent analyses have definitely shown that there is no added risk of polio to those children who have had a tonsillectomy Perhaps there remains some doubt regarding the bulbar type of case, but even this is questionable. We all agree that it would be hazardous to do optional surgery during an acute epidemic of any sort, and this statement includes any epidemic of poliomyelitis When there is a definite indication for removal of tonsils, those tonsils should be removed I still claim the surgical removal of tonsils and adenoids also acts as an important prevention measure in ear diseases, either of the infectious or the functional type

Sinusitis is frequently coexistent with hypertrophied and diseased tonsils and adenoids It is also a cause of recurrent adenoid tissue following adequate adenoidectomy Surgery on the sinus of a child is rarely necessary When I believe sinusitis is a cause of recurring lymphoid growth in the nasopharynx, I do at least one nasal treatment a day myself Occasionally, a mother will carry out treatment orders specifically, but, where one needs to be sure of the effectiveness of sinus treatment that by its effectiveness will produce an improvement in impaired hearing, it is better to do one treatment a day yourself and leave the rest, perhaps two or three treatments, to the mother A persistent sinusitis will be helped many times by a proper tonsillectomy and adenoidectomy when such operations are indicated

Tonsils seldom recur after they are properly removed, but adenoids do recur frequently following satisfactory surgical removal There is an explanation which sounds logical We are all familiar with the hypertrophied lymphoid streaks extending from the nasopharynx along the postpharyngeal wall medial to the posterior pillar of the tonsil I have always associated this condition with persistent sinusitis By posterior rhinoscopy, one can observe the nasopharynx and lateral walls around the fossae of Rosenmueller Similar growths or regrowths of varying sizes will also be found in these locations Surgical removal of this lymphoid tissue which is not followed by proper treatment of the sinuses is apt to be followed by a recurrence of lymphoid growth

Our adult patients with impaired hearing frequently give a history of recurrent continuous colds during childhood These recurrent colds suggest the third item in the causes of adult impairment in hearing It is a little early as yet to have brother otologists or other medical men accept the proposal that the recurrent attacks of upper respiratory disturbances arising from recurrent allergy attacks may be a major cause of progressive deafness, however, within my recollection, even the suggestion that allergy might

be the basis of some of our nose and throat diseases was dismissed with a sarcastic smile Today most otolaryngologists accept as a fact that allergy is at the root of much ear, nose, and throat pathology Therefore, in making the statement that allergy and impaired hearing may be in a "cause and effect" relationship, I realize how difficult it is, under present conditions, to accept it

I shall present for your consideration a few case histories from my private files to illustrate some of my statements I have not selected unusual cases, these are, for the most part, examples of the average

Case Reports

Case 1 —Suzanne F , aged seven and one-half, consulted me on February 18, 1947 Difficulty in hearing combined with repeated colds and sneezing attacks were the complaints A good removal had eliminated her tonsils Presumably, the pharyngeal adenoid tissue had been as competently removed Suzanne had many skin tests for allergy She showed a marked reaction to alternaria and a marked reaction to bananas Desensitization to alternaria plus allergen-elimination diet and local treatment produced this improvement in hearing

Case 2 —Joan S , aged nine, was a fat, apathetic, rather difficult child Her hearing was below the serviceable level. She was most uncooperative The nasopharynx was filled with adenoid tissue which had been subjected to previous surgery, and more was advised The nose was closed with blue-gray tissue, and the chunks were pus filled Her first visit was on May 13, 1947 Joan was sensitive to dust. She was desensitized Allergen-poor diet plus local treatment for the nose was used. The improved hearing which she obtained was accompanied by improvement in character On March 19, 1948, I have a note which reads, "The improvement in this girl's hearing has been rather phenomenal—her nose has entirely cleared under local and antiallergic methods for recurrent bad sinusitis Her whole personality has improved." Today Joan is quite a lady Her hearing chart shows her to be improved to within normal limits

Case 3 —Gail S , aged twelve, is probably the most dramatic case in this series Her complaint at the visit on December 28, 1945, was deafness in the right ear The duration was one year Small buried tonsils and pus in the nose were found in the physical examination A history of colds which lasted a long time made one suspicious of a sinusitis which the x-ray helped confirm Food elimination of the common allergenic ingestants plus local nasal medication put Gail back in the normal hearing group and reduced her disabling colds

Case 4 —Willie H , aged nine, was a physically underdeveloped boy of nine. Willie had a nice cooperative disposition, and he rewarded a doctor's best efforts with his appreciation I saw him first on February 6, 1948, and my letter to his doctor was, in part, as follows "Your very likable little Willie H has rather a pack of trouble I doubt that he has any hearing present at all in his right ear His left is diminished The right side of his nose is almost completely blocked by deflection of the nasal septum. The part of the nose that was not blocked was completely filled with pus

"I have started some treatment for his sinusitis, taken x-rays to determine its extent, and later will decide whether or not I think a submucus would be excusable at his early age I am afraid that nothing can be done for his hearing in the right ear, and our whole effort should be directed toward maintaining hearing in his left " My later note on May recommended a radical maxillary sinus operation and submucus resection These procedures were not done Diet, drops, and dumb luck did it again

Case 5 —There is no great loss of hearing in the case of Edward S , but his audiogram illustrates the type which I believe if unchecked would result in impairment later in life This boy is the only one with a discharging ear history He had frequent colds and recurrent ear involvement in the past, but both had improved during the current year His hearing was diminishing, and the school recommended a visit to his otologist I believe it saved Edward from an aural handicap Seven and one-half years was his age at the time of his visit August 12, 1948 The usual treatment brought a lowered hearing up to within normal limits

Case 6 —A tonsillectomy and adenoidectomy did the trick for this youngster K G was age seven at the time of the first visit on January 8, 1949 The patient had suffered from blocked nose and nasal discharge during January and December since the age of one There was occasional pain in the ears plus difficulty in hearing for the past two months The mother was a hay fever patient The nasal mucous membranes of the patient were pale As a first step in the cure, an adenoidectomy and tonsillectomy were done January 12, 1949 An audiogram taken February 12 (one month later) shows the quick recovery of hearing to within normal limits

Case 7 —Lois T , aged thirteen at her first visit on September 27, 1948, is the seventh and last of this series I am presenting She was sent from school with an impaired hearing record She had had difficulty in hearing since myringotomy at the age of seven. In my note to the referring physician I stated, "She has a slight impairment of hearing in the conversational area which I believe to be due to a low-grade sinusitis which has caused a hypertrophy of lymphoid tissue in her nasopharynx." Lois weighed 113¼ pounds on November 8, 1948, and on February 22, 1949, the weight was 123 pounds Her swollen adenoid tissue has subsided, and her sinuses have stayed clear She received 1 per cent ephedrine in normal saline as nasal medication and allergen-poor diet, and that is all The hearing is now within normal limits

Comment

These seven cases are samples of what can be done by medical, surgical, and allergic care in these patients Even adults have shown favorable responses when the impairment in hearing has not progressed too far

The real hitch in producing results is the failure to identify and take proper cognizance of the child with early hearing impairment The doctor has failed to place enough importance on slight hearing impairments in the young There is a psychologic factor which often makes a doctor shirk his responsibility We just hate to tell parents that their child is losing his hearing Action is needed on the first day any auditory impairment is noted Any involvement of the ear should be followed by repeated tests of the hearing function

The broader step is more important and involves unremunerative work of the most tedious order Every child of school age should have a hearing test on entrance to school, and these tests should be done annually as a matter of routine If this routine testing becomes just a part of some system to build up a pile of dust-covered records, then all efforts are wasted We went through this sanctimonious self-satisfying conscience soporific in New York State, piles and piles of pure statistics on which little action was taken to help the individual child We have now established a sufficient number of conservation of hearing clinics to do real work in solving the hearing problems of our individual patients And *this work must be on the individual basis in order* to obtain results Assembly line methods to accumulate statistics are worse than useless

"The hard of hearing problem"—we have that phrase so rubber stamped it does not occur to us that our next door neighbor and friend has a child who is the hard of hearing problem, probably not given proper attention until too late "They will grow out of it," you tell the patient Your sealed verdict may sentence that child to permanent hearing loss If you do not know what can be done for the aurally handicapped or potentially handicapped child, by all means find out

The congenitally deaf child is a continuing problem for all concerned It takes the finest type of parents to cooperate in a teaching program and the highest type of aurist to help the parents see it through Any attempt on the part of either the doctor or the parents to avoid responsibility will have unmeasurable adverse effects on the deaf child Unfortunately, the otologist in too many instances dodges his responsibility by trying to "pass the buck" in this unremunerative and time-consuming field Many times these children respond to understanding sympathies, and e traordinary results are produced It is well to r member that, even the deaf children can be ma self-supporting, they can enjoy social contact and they become agreeable companions if the are properly directed Some show an unexpecte ability to adjust themselves and overcome the handicap Means of communication must b furnished them, and their first instruction mus of course be along those lines

The usual child with impaired hearing is muc *better adjusted to his handicap if permitted t* continue with normal children The use of hearing aid, instruction in lip-reading, and an advantageous position in the classroom will enable these children to meet or exceed the performance of unhandicapped pupils in their age group Much depends on the teacher And this point should be carefully investigated before any school is recommended The unusual problems are best handled by individual instruction Small groups working with a competent teacher seem to progress most satisfactorily Like ourselves, the schools for the aurally handicapped are apt to fall behind, using outmoded, stereotyped methods, rather than taking advantage of the unbelievably rapid progress in methods to aid the aurally *handicapped* The development of speech for the deaf child is a major problem which is best managed by a competent speech teacher to whom small groups are assigned The association in small groups seems to give the individual patient courage and confidence

To obtain the maximum result with the hard of hearing child I only echo Wishart's opinion, "The otologist must approach the patient in the proper frame of mind, must have the means and environment for measuring hearing, must be prepared to examine the patient many times *before expressing* a final opinion, and must do the work himself "[1] In conclusion I will emphasize his thought and say that an otologist will not get the best results with his small patients who have hearing problems unless he does the work himself and treats them as individuals and individual patients

WARN OF ILL EFFECTS FROM OVERDOSES OF ASPIRIN

A warning that aspirin acts as a poison when taken in too large doses is given by three Philadelphia doctors Excessive amounts of the drug have a toxic effect on the brain, kidneys, and other organs, Drs Bernard L. Lipman, Sidney O Krasnoff, and Robert A Schless point out in the October issue of *American Journal of Diseases of Children*

They report five cases of poisoning from overdoses of aspirin Three patients were children, and there were two deaths in the series

PEDIATRIC SUGGESTIONS TO REDUCE NEONATAL MORTALITY

MANFRED WEICHSEL, M D , and JOSEPH H LAPIN, M D , New York City

(From the Pediatric Service of Greenpoint Hospital and the Department of Pediatrics, Bronx Hospital)

THE reduction of infant morbidity and mortality cannot be accomplished by pediatricians alone, since only about one fourth of all infants are under the medical supervision of pediatricians Although infant mortality rates have shown a remarkable decline in the last decade, the neonatal death rate has been reduced only 10 per cent from 1916 to 1934.[1] Of the total number of deaths during the first year of life, more than half occur during the first twenty-four hours, according to data compiled by the U S Bureau of the Census Therefore, a better understanding, by the obstetrician or any physician taking care of the newborn infant, of certain preventive aspects of modern pediatrics may materially reduce the mortality rate of the newborn The effects of the obstetrician will greatly influence the hazards during the first twenty-four hours and the ultimate prognosis The anatomic findings of the causes of fetal and neonatal deaths reported in some recent studies supply a basis for making recommendations on methods for reducing the number of these deaths [2–6]

Notwithstanding a remarkable fall in the mortality rate from prematurity, this condition represents still the chief cause of neonatal deaths in the United States It is responsible for from 19 1 to 49 5 per cent of neonatal deaths in the reports cited Although prematurity per se is not necessarily associated with high mortality rates, immaturity of various organs and of the temperature regulating mechanisms present a serious handicap To reduce mortality from premature birth, steps have been advocated to diminish the incidence of premature birth as well as methods for improving the care of the premature baby after birth Conservative obstetric practice is opposed to the performance of procedures which interfere with the birth of a viable infant, and it strives to prolong intrauterine life as long as possible Thus, the extra hazard of prematurity resulted in obstetric disapproval of early interference as a means for reducing erythroblastosis A six-months pregnancy complicated by placenta previa should not be terminated by cesarean section at this stage unless absolutely indicated to save the mother's life There are indications that low forceps and episiotomies often do less harm in premature birth than so-called normal deliveries

The cause of prematurity may be considered under four headings acute infections such as pneumonia, pyelitis, gonorrhea, chronic disorders such as heart disease and nephritis, inadequate diet of the pregnant mother, and obstetric complications The acute infections deserve far more intensive chemotherapy or treatment with antibiotics than has been the usual procedure heretofore Of the chronic disorders, competent medical care of the patient with cardiac conditions, hypertension, diabetes, etc should reduce the number of premature births The obstetric complications like premature rupture of the membranes, placenta previa, vaginal and cervical infections uterine fibroids, etc , require the exercise of mature judgment in balancing the danger to the mother's life against the danger of prematurity The figures on the influence of an inadequate diet in pregnancy on prematurity are impressive [6] The diet to be recommended should contain protein, 85 Gm or more, calcium, 1 5 Gm , phosphorus, 2 0 Gm , iron, 20 mg , vitamin A, 8,000 units, thiamine, 2 0 mg , riboflavin, 2 5 mg , niacin, 18 mg , ascorbic, 100 mg , and vitamin D, 400 to 800 units

In spite of all efforts to carry the pregnancy to full term, many will end prematurely The question arises How may the obstetrician aid in reducing the mortality and morbidity of the premature baby? Recommendations include determination of the size of the baby at the onset of labor, preservation of the membranes as long as possible, and episiotomy, elimination of inhalation anesthesia, morphine, scopolamine, and barbiturates, and the administration of vitamin K and oxygen to the mother during labor [7–9] Regional nerve block anesthesia has been shown definitely to offer the premature infant its best chance for survival [10] A heated crib for the reception of premature infants should be on hand The continuous administration of oxygen during the first hours after birth is advocated, and infection should be eliminated as much as possible by prophylactic chemotherapy The early administration of vitamins A, B, C, and K and the use of a half-skimmed, dried milk powder formula have materially helped in the feeding problems of the prematures [11,12]

Next to prematurity per se as a cause of death are respiratory conditions or anoxia [2–5] Deaths in 10 9 per cent of prematures and from 16 to 28 per cent of full-term infants resulted from massive aspiration of amniotic fluid, the higher figure in the latter group reflecting the longer, more difficult deliveries Asphyxia and atelec-

tasis are the chief concern [13,14] Abnormal conditions in the mother, as well as pathologic conditions in the infant, are mainly responsible for asphyxia

Certain positive recommendations can be made First, where the fetus is in obvious distress, early delivery is indicated Second, the use of oxytocics, sedatives, and morphine late in labor should be avoided Third, nitrous oxide should not be given unless 15 per cent oxygen is added [15] Fourth, if there is evidence of fetal embarrassment, oxygen should be supplied to the mother in high concentrations Fifth, every newborn baby should be held head downward—unless there is reason to suspect cerebral hemorrhage—while a careful toilet of the nose and throat is done with a soft rubber catheter and gentle suction Roberts, who found that the use of paraldehyde did not increase infant mortality, considers mechanical resuscitators of doubtful value "Positive pressure up to 16 mm of mercury with negative pressure to 9 mm of mercury is advocated Such pressure at times appears incapable of expanding the neonatal atelectatic lung and yet at other times seems sufficiently great to cause alveolar rupture and emphysema "[5] He depends on mouth-to-mouth resuscitation and occasionally on the endotracheal catheter Flagg advocated the use of an endotracheal catheter in the stage of flaccidity because the glottic structures are collapsed [16] The cathether is used for suction as well as administration of oxygen It may be inserted either under direct laryngoscopy or by palpation While Torpin states that 6 to 10 per cent of infants require such intubation, other investigators consider the method harmful and unnecessary [17] Gentleness and external warmth are advocated in all these procedures

Death in another 7 8 per cent of the prematures and 20 8 per cent of the full-term infants results from pneumonia [2-5] In the majority of the premature infants the cause is given as aspiration pneumonia This complication, resulting almost entirely from aspiration of milk, may be due in some measure to unskilled gavage but in great measure to the iniquitous habit of propping up the bottle in the crib As a consequence, the newborn, while feeding unassisted, may choke on the milk and suck in enough to produce a rapidly fatal aspiration pneumonia Careful attention to nursing details should serve to keep this group down to a bare minimum The other pneumonias are bacterial and are probably due to aspiration of infected amniotic fluid It seems reasonable to suppose that the routine use of penicillin in the mother after the rupture of the membranes would appreciably reduce the number of these bacterial pneumonias

The next most frequent cause of neonatal death is birth trauma, accounting for 12 8 per cent of the prematures and 23 9 per cent of the full-term infants [2-5] Intracranial hemorrhage may occur in spontaneous deliveries but usually results from trauma, asphyxia, or low blood prothrombin concentration Faber found a high incidence of prenatal factors responsible for cerebral injury in cases of cerebral atrophy [18] These children showed mental deficiency, spastic paralysis, or the convulsive state The factors responsible included placental separation, toxemia, Rh incompatibility, oversize infant, premature rupture of the membranes, maternal trauma, infectious disease, and many cases of difficult deliveries, breech deliveries, and abnormalities of the cord Prophylactic measures include better obstetric management and administration of vitamin K during labor

Congenital anomalies were responsible for *death in 6 5 per cent of the prematures* and 1 06 per cent of the full-term infants [2-5] The prevention of congenital anomalies has assumed increased importance in the past few years The susceptibility of embryonal tissue to virus infections is well known and the effect of rubella in the pregnant mother on the infant well established Among the serious disturbances are congenital cataracts, cardiac lesions, deafness, microcephaly, and mental retardation Deliberate exposure of older girls to rubella has been suggested with a view to producing immunity The significance of other infections in causing congenital malformations is doubtful, toxoplasmosis in the mother, however, may cause anomalies in the infant Other causative factors include pelvic radiation and nutritional deficiencies [18-23] Noxious agents affecting early embryonal development may cause mongolism [24] Hemorrhage, threatened abortion, intercurrent infections, mechanical disorders, and tumors of the uterus are mentioned among the causative factors All anomalies found in mongolian idiots appear to arise in the sixth to ninth week of embryonal development

While not all of these congenital malformations are preventable at present, the outlook for some of the affected infants has improved recently due to better surgical technic Early recognition of these defects, however, is imperative The most important ones affecting the gastrointestinal tract may be mentioned

1 Congenital atresia of the esophagus of which there are several varieties There is prompt regurgitation of attempts to swallow food, and fluids return through the nose and mouth. A simple examination by means of a soft catheter passed into the stomach will usually reveal the obstruction If roentgenographic stud-

ns are considered necessary, iodized oil rather than barium should be instilled into the upper egment There is usually gaseous distention of the stomach

2. Atresia and stenosis of the small intestine There is greenish-brown, often chocolate-like vomiting and cornified epithelial cells and lanugo are absent in the stools X-ray findings are characteristic There may be malrotation of the colon with the cecum on the left side, obstructions due to volvulus, or constricting peritoneal bands

3 Diaphragmatic hernia Characteristic signs include cyanosis, sunken abdomen, rapid respiration, dyspnea, and overdistended chest

4. Malformation of anus and rectum occur occasionally and should be diagnosed immediately, since an early operation is an absolute necessity

The influence of the mother's health and nutritional status on prematurity has already been discussed but must be adequately considered in the prevention of neonatal deaths in the full-term baby as well Thus, adequate antiluetic treatment, the skilled management of tuberculosis, cardiac and nephrotic lesions, frequent hemoglobin determinations, endocrine therapy when indicated, appraisal of the size of the fetal head by x-ray examination, and good obstetric management are all important factors The child of a diabetic mother needs special care in the regulation of the blood sugar of the pregnant mother and estrogen therapy where indicated [25]

The figures for neonatal death due to sepsis approach the vanishing point Many institutions now practice prophylactic administration of penicillin, especially to premature infants

Minimizing deaths from erythroblastosis requires a definite plan Rh testing should be done early in pregnancy, and the Rh negative mothers and those Rh positive mothers with a history suggestive of *erythroblastosis* should have a repeat Rh test and an Rh antibody titer test In questionable cases, titers should be repeated monthly and the other appropriate tests done. In addition, all newborns with jaundice within the first twenty-four hours, pallor, and splenomegaly should be investigated thoroughly So-called replacement transfusions have recently been used more extensively The indications should be clear-cut demonstration of antibodies in the mother's circulation, anemia, edema, jaundice, splenomegaly, hepatomegaly, and a high nucleated red cell count Diamond has described a mode of transfusion by using the umbilical vein by means of a special catheter which appears to be safer and easier than the older methods [26] Perhaps of more importance is good pediatric and nursing care of these infants, especially in regard to infection and aspiration [27] They should be treated in the premature nursery where greater emphasis is laid on the care of apathetic infants

The question of preventing infections in the nursery, notably the outbreaks of epidemic diarrhea and skin infections, is complicated and has received a great deal of attention Our knowledge of epidemic diarrhea of the newborn is limited, some investigations indicate a virus cause Steps to prevent infections as summarized from the "Standards and Recommendations for Hospital Care of Newborn Infants" of the American Academy of Pediatrics Committee on Fetus and Newborn include the following

1 Health examination of physicians, nurses, and auxiliary workers, including x-ray of the chest and bacteriologic cultures of nose throat, and stool

2 At least one graduate nurse supervising and at least one nurse or aid for each 12 full-term infants

3 One nursery for normal full-term infants, one or more suspect nurseries, and a proper isolation unit

4 Twenty to 30 square feet per bassinet with 8 to 12 bassinets in each full-term nursery and only six in suspect nurseries

5 Bassinet, bedside table with drawer, and a lower compartment, all together or as a single unit

6 Formula room with aseptic control and terminal sterilization

7 Prematures Six hours nursery care per twenty-four hours, should have at all times, day and night, nurses (or aids) in a ratio of one nurse for each four infants (for present emergency six infants allowed)

8 Separate premature nursery with separate provisions for infants born out of the hospital, for suspect infants, and for isolation

9 Premature nursery with no more than six bassinets with 30 square feet per bassinet

The interest of the obstetrician in physical equipment and facilities for the care of newborn infants is obvious In the construction of new hospitals, special attention is paid to the maximum number of bassinets allowed in one nursery on the principle that newborn infants should be in small groups and should have adequate space The avenues of cross-infection are being studied, and contact cross-infections by nurses, interns, attending physicians, mothers, and visitors can easily be reduced [28] Detailed recommendations should be studied by everyone interested in preventing infections in the newborn [29] To prevent airborne cross-infections, air conditioning, in order to dilute or eliminate contaminated air, and ultraviolet radiation, as well as glycol vapor, have been advocated and are now being studied [30] Premature infants thrive better in an atmosphere of relatively high humidity The optimum temperature is between 80 and 90 F , and a humidity of about 60 per cent is desirable Individual incubators with accurate control of temperature

and humidity which allow changing of the diapers and handling of the baby without opening the incubator will diminish airborne infections

So-called rooming-in arrangements where mother and baby are in the same room close to each other have obvious advantages because the mother learns to know her child better before her discharge from the hospital, the father may get acquainted with his child at an early stage, the mother is allowed to have her baby by her bedside as often as she desires, breast feeding is promoted, and the danger of communicable disease is lessened

There are several other preventive measures of interest to the obstetrician which may aid in reducing morbidity in infants Active sensitization of the infant by antigen transmitted through the placenta may occur quite frequently and has been demonstrated in animal experiments [31] Ingestion of food protein by the pregnant mother may be responsible for allergic reactions observed in infancy For this reason, the pregnant mother should limit her intake of allergenic foods such as eggs, fish, chocolate, nuts, etc

Another important problem the obstetrician may have to deal with is prenatal immunization against some contagious diseases of childhood While the newborn infant is immune against measles, poliomyelitis, diphtheria, and scarlet fever, he shows no resistance against tuberculosis, varicella, and whooping cough The long-standing belief that young animals respond poorly to antigens led to the delay of many active immunizations until the second half of the first year of life This would make it impossible to provide adequate protection against pertussis at a time when it is most needed Although a certain percentage of pregnant mothers exhibits antibodies against pertussis, the corresponding titer in their babies appears to be insufficient to confer immunity, and even after immunization this titer drops to zero over a period of several months [32 33] Prenatal immunization against pertussis has been performed by giving injections of pertussis vaccine during the last trimester of pregnancy [34] Whether the titer of these passively transmitted antibodies is sufficient to protect the baby against pertussis is questionable Studies are in progress to determine whether the presence of these passively transmitted antibodies will interfere with the active production of antibodies against Hemophilus pertussis and thereby cause postponement of active immunization until the latter part of the first year of life Another aspect of this problem, obviating the need for prenatal immunization, is the successful demonstration of active immunization of very young infants [35 36] These experiments seem to indicate that young infants are capable of producing antibodies against pertussis just as well as older children, especially if alum-precipitated vaccine, which affords prolonged antigenic stimulus, is used. The disadvantages of immunizing pregnant mothers against pertussis apply also to prenatal immunization against diphtheria The change of the immunologic state of the population against diphtheria is well known [37] Due to the decline in the number of diphtheria carriers a greater percentage of the adult population became susceptible to infection In this country about half of the newborn infants have protective titers against diphtheria, while in Sweden only 10 per cent are immune [38] Since, however, diphtheria is rare in young infants and, on the other hand, protective levels of diphtheria antitoxin may be attained by active immunization of young infants, no routine immunization of pregnant mothers can be advocated at this stage

The authors are indebted to Dr H Sternberg for his valuable suggestions in the preparation of this manuscript

THE RELATION OF THE POSTCHOLECYSTECTOMY SYNDROME TO PSYCHOSOMATIC MEDICINE AND TO LATENT SUBCLINICAL FORMS OF CLINICAL DISEASE

ABRAHAM O WILENSKY, M D ,* New York City

THE last decade has witnessed much discussion of the rather frequent recurrence of symptoms after the operative removal of the gallbladder These always include complete enumerations and discussions of the unfortunately common, operatively produced or other anatomic lesions which are discovered secondarily, as well as of the cases in which calculi are again demonstrated, found, and removed at subsequent operations While the results of all of this secondarily performed surgery have, in many cases, been brilliant, it, nevertheless, is in no sense a discussion of the symptom complex, which has been described under the term of the "postcholecystectomy syndrome" The discussion in this communication concerns only the latter

The postcholecystectomy syndrome includes symptom complexes in which (1) the manifestations frequently and commonly repeat with greater or lesser similarity those present before the cholecystectomy was done and (2) an indefinite array of symptoms referred to the right side or upper right quadrant of the abdomen which do not seem to be indicative of any distinguishable localized intra-abdominal lesion Clinical study by means of physical examination and by all methods of laboratory examination yield no enlightening data. One is left with many symptoms for which no adequate anatomic or functional cause can be found This is what is meant by the postcholecystectomy syndrome

It is manifestly true that, when such symptom complexes appear or reappear after cholecystectomy, under the conditions just defined, somewhere along the path of original study a mistake has been made and the presenting symptoms have been wrongfully correlated with gallbladder disease In this connection it is very true that (1) not all radiographically demonstrable gallstones are productive of symptoms in general and of the individual subjective symptoms of the given patient in particular, (2) some of the cases without calculi or other demonstrable anatomic lesion before the primary cholecystectomy may be cases of gallbladder and biliary tract dysfunction which possibly can, and do, produce subjective symptoms, and (3) the latter group may, and probably do, include cases with latent or subclinical forms of hepatic—cellular or interstitial—disease (*vide infra*)

Clinical experience, as determined by adequate follow-up studies, indicates very strongly that the "postcholecystectomy syndrome" symptoms very rarely, or perhaps never, have occurred when the primary preoperative lesion has included anatomic evidences of acute and chronic infection, and the more marked this has been, the more true is this statement These are the cases which give the best and most reliable results after cholecystectomy

One must study the patient from every angle when the postcholecystectomy syndrome is present In cases with this clinical picture, i e , when no adequate anatomic lesion is demonstrable, one is forced to conclude many times, at least until further observation possibly demonstrates otherwise, that there is a psychiatric background for the manifestations and that the patient is in need of psychotherapy As knowledge of psychosomatic medicine accumulates and is applied to some of the constantly occurring problems of this kind, manifold examples are found in which emotional conflicts have been very important items, and to these it behooves one to pay sufficient attention There is much in psychosomatic medicine and in psychiatry today to corroborate this viewpoint

This group of cases undoubtedly includes instances—I cannot say how many or how often—of latent or subclinical forms of hepatic cellular or hepatic interstitial disease And for these one must constantly be on the lookout, for the powerfully important reason that for them modern forms of therapy are productive of greater good and, possibly, of cure at this subclinical stage than at later stages This is one of the accomplishments of modern medicine and did not seem possible ten or twenty years ago The notes of the following case are very pertinent here

Case Report

In 1933, when this married, Para 2 woman was in her early fifties, she was ill with a form of nephritis, the nature of which I do not know, and from which she presumably recovered

In 1936, she exhibited symptoms, referable to the upper right quadrant of the abdomen, which were roentgenographically and laboratory wise correlated with gallbladder calculus disease without signs of

* Dr Wilensky died on February 4 1949 Therefore only editorial corrections have been made on this manuscript

any acute or chronic infection I operated on her at that time, and the operative findings included (1) a thin-walled gallbladder containing a large number of small cholesterol and biliary calculi, (2) an extrahepatic duct system which was negative to palpatory exploration, and (3) a beginning hob-nailing of a relatively normal sized liver The pancreas and associated lymph nodes were also negative The spleen was not enlarged and was presumably considered not otherwise altered The rest of the abdominal cavity and its contained organs were also negative to exploration

The matter was taken under advisement, and the situation was explained to the patient However, in the profundity of our therapeutic lack of knowledge at that time, nothing further was done Following a relatively easy and uncomplicated recovery from the cholecystectomy, the patient felt relatively well for the next ten years

In 1946, the woman developed an anemia of the secondary type, and it was discovered that she was passing large amounts of blood in the stools A large hard liver and an enormous spleen were easily palpable For the next two years the symptoms and signs progressively increased until she finally died The diagnosis was Banti's disease with splenomegaly and hepatic cirrhosis Unfortunately, no postmortem examination was permitted

Comment

It is undoubtedly true that the final illness was the progression of the liver lesion which was found at the primary exploration in 1936 It is equally true that the original diagnosis was not altogether correct and that whatever symptoms she presented at that time were not entirely due to the gallbladder stones but to a subclinical stage of the disease from which she finally died twelve years later

It is not always possible to find such gross structural evidences of hepatic disease at the primary exploration When present, they are generally mild, have, perhaps, to be passed over, and/or are held of little significance Unfortunately, they are commonly considered not worthy of further study, concern, or therapeutic application

Nevertheless, in all postoperative cases with this syndrome, the factor of an underlying subclinical form of hepatic parenchymal or interstitial disease must be considered It follows that in the absence of the signs of acute or chronic infection all preoperative cases also carry the suspicion of the possibility of a similar latent hepatic disease It becomes obligatory, therefore, for us to deny or establish such disease in every case both before and after cholecystectomy so that proper precautions and therapeutic measures may be taken

At the present writing, subclinical or latent forms of liver disease only show indications of their presence by disturbances of liver function No one method seems to answer the clinical purpose, and no single determination is of any diagnostic use What is needed is a series of consecutive determinations of liver function by more than one method inasmuch as all are not of equal accuracy Should evidence of latent or subclinical hepatic disease be shown by these means, the patient must be informed of the existing state of affairs so that proper modern methods of therapy may be employed The latest experience has demonstrated that the progress of the disease may be halted, and a cure may possibly follow

Summary

The postcholecystectomy syndrome includes the patients who have a frank recurrence of their precholecystectomy symptoms or of other indefinite symptoms referred to the right side or upper right abdominal cavity The postcholecystectomy syndrome seems to be proof that the original diagnosis was an error The patients fall into two categories those who seem to have a psychosomatic background for their symptoms and those with subclinical or latent forms of hepatic cellular and/or interstitial disease The recognition of the latter is important because at this state modern therapy seems to be able to do very encouraging things

RESEARCH FIXES LIMITATION OF MAN'S ALCOHOL CAPACITY

Any one on a daily ration of a quart of 100 proof whisky would show obvious signs of intoxication, says an editorial in the August 13 *Journal of the American Medical Association*

The editorial is a commentary on man's capacity for alcohol and is based on a recent study by Dr Henry W Newman of the Stanford School of Medicine, San Francisco Dr Newman for the first time presented an accurate standard of human capacity for the consumption of alcohol

His research indicated that a man weighing 154 pounds can metabolize (convert into energy) about 26½ ounces (about one fifth) of 100 proof whisky in 24 hours Any definite increase in this amount would raise the alcohol content of the blood and brain to a point where coma would supervene This limit could be exceeded only for a brief period, probably a matter of hours

It is also stated that the idea that habituation produces increased facility in metabolization is not supported by scientific evidence Large and heavy persons can consume more but merely on account of their bulk and not because of any increase in ability to metabolize alcohol

Case Reports

COXITIS DUE TO ESCHERICHIA COLI

W R PETERSEN, M D , Albany, New York

(From the Edward J Meyer Memorial Hospital, Buffalo, New York)

THE case to be reported below is the fourth recorded since 1936 in which Escherichia coli is the cause of a destructive arthritis of the hip [1–3] Three of the four cases, including the one below, were known to have had urinary infection due to E coli, presumably as the primary infectious focus

Case Report

K. L., a sixty-seven-year-old white man, was admitted to the Edward J Meyer Memorial Hospital on April 21, 1948, complaining of increasing pain in his right hip, which had never been able to take his full weight since a fracture and subsequent operative treatment at Cook County Hospital in 1943 Functional inquiry revealed frequency of urination, nocturia, and dysuria, present for eighteen years and progressive

Physical examination revealed a moderately ill, elderly white man, temperature 100 4 F , pulse 110, respirations 24, and blood pressure 160/100 Positive findings included rales in the bases of both lungs, an enlarged heart, distention of the bladder, and benign prostatic hypertrophy The right hip presented a long, curved anterolateral scar, marked swelling anterior to the joint, semifluctuant and mildly tender to pressure, and marked pain on attempt at active and passive motion in any direction There was an external rotation deformity and 2 inches shortening of the right lower extremity Pretibial edema was present bilaterally

The right leg was placed in Buck's extension, and an indwelling catheter was inserted into the bladder. Parenteral Ringer's solution and plasma were given daily for uremia Aspiration of the right hip produced 150 cc of bloody pus Penicillin was then given while awaiting the result of culture The pus, as well as blood and urine, yielded a short, gram-negative bacillus on culture which produced much mucoid material and which was identified as a modified E coli [4]

The organism was found to be sensitive to streptomycin, but the drug could not be given because of progressive uremia On May 6, 1948, incision and drainage of the right hip was done under local anesthesia An incision made directly anterior over the hip joint entered a huge abscess beginning about 1 inch from the skin The abscess extended high into the pelvis posteriorly and down to the lesser trochanter and adductor region inferiorly About 1 L of slimy blood, pus, and debris, and a bony spicule were removed. The head of the femur was palpated and found to be devoid of soft tissue attachments anteriorly The upper end of the metallic fixation agent was in the abscess cavity The day after incision, profuse drainage of another liter from the abscess necessitated change of dressing Later on the same day the patient expired

Laboratory findings were as follows Urinalysis —specific gravity 1 015, albumin 1 plus, no sugar,

FIG 1 Note necrotic head, narrowed joint space, and nonunion of fracture

many pus cells, blood urea, 98, 111, 206, 241, carbon dioxide combining power, 22, hemoglobin, 6 8 Gm , red cell count, 3,000,000, Wassermann negative, serum protein 6 6 per cent Figure 1 is an x-ray of the right hip

An autopsy was done on this patient The kidneys and renal pelves were found to be the site of an active chronic ascending pyelonephritis with multiple scars, destruction of renal parenchyma, and slimy pus secondary to prostatic obstruction of long duration There was an abscess of the right psoas muscle, extending to the muscle origin at the lumbar spine, distinctly separate from the right kidney and ureter and extending inferiorly to the hip joint, greater and lesser trochanters, and the adductor region of the thigh The abscess measured 38 by 7 by 6 cm The old fracture was ununited The cartilaginous surface of the head was irregularly eroded and covered with much purulent material Postmortem cultures of the abscess and renal pelves produced the same organism as antemortem cultures

Comment

This patient probably developed his septic process in the right hip region at some time after his early postoperative period. He undoubtedly had a latent chronic pyelonephritis with recurrent exacerbations and occasional bacteremia The injured and operated hip was a locus minoris resistentiae where the metastasizing organism could create an active low-grade infection The low virulence of the organism and the resistance of the host due to prolonged urinary infection with the same organism allowed the infectious process to develop gradually, probably over a period of months or years The same factors also are assumed to have modified an organism which was originally a typical E coli The patient did not seek medical care until his last hospital admission when progressive renal destruction with uremia allowed his other disease process to develop more rapidly and become acutely symptomatic

At his last admission, the renal changes were irreversible Streptomycin could not be used Blood donors were unobtainable Incision and drainage of the abscess and urologic treatment were too late by months or years

Summary

A case of coxitis due to E coli is reported with autopsy findings and discussion of course and probable mechanism of the disease process

PRIZE ESSAYS

The Merrit H Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York, May 8, 1950, in New York City

The Lucien Howe Prize of $100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology The author need not be a member of the Medical Society of the State of New York

The Merrit H Cash Prize of $100 will be given to the author of the best original essay on some medical or surgical subject Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State

The following conditions must be observed

Essays shall be typewritten or printed with the name of the prize for which the essay is submitted, and the only means of identification of the author shall be a motto or other device The essay shall be accompanied by a sealed envelope having on the outside the same motto or device, and containing the name and address of the writer

If the Committee considers that no essay or contribution is worthy of a prize, it will not be awarded

Any essay that may win a prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented not later than February 1, 1950, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York 17, New York

Armitage Whitman, M.D , *Chairman*
Committee on Prize Essays

FULMINATING MENINGOCOCCEMIA (WATERHOUSE-FRIDERICHSEN SYNDROME) WITH RECOVERY

R. WILLARD BRAND, M D , Clifton Springs, New York

(From the Medical Service of Clifton Springs Sanitarium and Clinic)

SOME 25 cases of recovery from the so-called Waterhouse-Friderichsen syndrome have been reported in the literature [1-6] The term Waterhouse-Friderichsen syndrome was applied originally to the postmortem observation of bilateral adrenal hemorrhages in cases of fulminating infection having widespread purpuric rash and signs of circulatory failure The causal relationship between the adrenal hemorrhage and the clinical shocklike picture seemed apparent However, Williams observed adrenal hemorrhage at autopsy in only nine of 17 fatal cases clinically indistinguishable from this syndrome [7] Furthermore, in view of the increasing number of recovered cases reported it seems permissible to infer that all patients presenting the clinical characteristics of fulminating sepsis, purpuric rash, and shock do not necessarily have bilateral adrenal hemorrhages The syndrome should, therefore, be regarded as potentially reversible by proper treatment This case is presented as an example of complete recovery from severe and prolonged shock occurring with fulminating meningococcal infection.

Case Report

History —A forty-nine-year-old housewife was admitted on April 27, 1946 Three previous admissions between April, 1931, and August, 1945, had been for acute pyelitis, appendicitis, and peptic ulcer, recovery from each of these conditions having been satisfactory Previously feeling well, the patient was awakened about 4 00 A.M of the day of admission by a severe, shaking chill, nausea, and vomiting She was seen soon after by her family physician, who reported finding no abnormality other than an oral temperature of 101 F She was given 1/4 gram of morphine, after which she went to sleep Later that morning she complained of moderate headache and pain and soreness in the joints She was brought to the hospital that afternoon because she could be aroused only with difficulty

Physical Examination.—On admission, about twelve hours after the initial symptoms, her temperature was 105 6 F , pulse 110, respirations 35, no blood pressure could be obtained The patient was semicomatose and in lucid intervals complained of generalized aching and soreness The entire body was covered with petechiae varying in size from pinpoint to 0 5 cm in diameter Her pupils were pinpoint A mucopurulent discharge was seen in the pharynx petechiae were noted over the soft palate The ears were normal The neck was supple, no Kernig sign was present, the reflexes were normal The lungs were clear and resonant, the heart was normal except for sinus tachycardia, and the abdomen was not remarkable Later, cyanosis and Cheyne-Stokes breathing developed. Further petechiae appeared, and purpuric areas developed over the entire body, those on the legs becoming confluent, extending over areas as large as 15 by 20 cm by the second day The patient had to be restrained because of extreme restlessness Peripheral circulatory collapse was severe, and considerable difficulty in starting intravenous therapy was encountered. Stiffness of the neck did not develop until twenty-eight hours after the onset of the initial chill

Laboratory Studies —The initial laboratory studies revealed erythrocytes 5,190,000, hemoglobin 15 1 Gm , leukocytes 8,400, with 70 per cent neutrophils, 27 per cent lymphocytes, 2 5 per cent monocytes, blood sugar 130 mg per cent, and urea nitrogen 18 mg per cent Voided urine showed specific gravity of 1 020, a trace of albumin, and occasional red and white cells per high powered field The spinal fluid was cloudy and contained 5,000 leukocytes with 90 per cent polymorphonuclears Gram-negative, intracellular diplococci were seen on direct smear, a culture later revealed them to be meningococci. The spinal fluid sugar was 20 mg per cent On the second day of admission the white count was 29,100 with 76 5 per cent neutrophils and 22 per cent lymphocytes, 1 per cent monocytes, and 0 5 per cent basophils A catheterized urine specimen showed a specific gravity of 1 017, albumin 2 plus, occasional red and white cells per high powered field, and 3 to 4 finely granular and hyaline casts per high powered field The urine culture was negative A blood culture, not obtained until after chemotherapy was started, was sterile

Treatment —The patient was started on penicillin, 50,000 units intramuscularly every three hours and also received 4 5 Gm of sodium sulfadiazine intravenously, as well as adequate amounts of intravenous saline and sodium lactate solution The penicillin was continued through the eighth day, and the sulfadiazine was continued orally for thirteen days, a dosage of 0 5 Gm every four hours becoming sufficient to maintain an average blood level of 8 mg per cent During the first twenty-four hours the patient received a total of 50 cc of adrenal cortical extract intravenously, during the same time intravenous fluids were administered almost constantly Sufficient fluid intake was accomplished orally after forty-eight hours, and the urinary output was never below 2,000 cc per twenty-four hours during the first ten days of therapy and remained normal thereafter

Course —The patient's blood pressure remained unobtainable for twelve hours after admission but gradually rose to normal in the next twenty-four hours The temperature fell to 100 F in the first twenty-four hours and then fluctuated between 99 and 101 F for two weeks, finally remaining consistently normal during the third week and thereafter For the first seventy-two hours the patient was restless and intermittently irrational. In lucid intervals she complained of severe headaches, generalized aching, and hyperesthesia throughout the body Oxygen was necessary to combat cyanosis from the third through the fifth day Signs of moderate pulmonary congestion appeared on the second day associated with dyspnea, cough, and occasional blood-tinged sputum which contained only a few nonpathogenic organisms A chest x-ray on the fifth day showed moderate passive congestion

many pus cells, blood urea, 98, 111, 206, 241, carbon dioxide combining power, 22, hemoglobin, 6 8 Gm , red cell count, 3,000,000, Wassermann negative, serum protein 6 6 per cent Figure 1 is an x-ray of the right hip

An autopsy was done on this patient. The kidneys and renal pelves were found to be the site of an active chronic ascending pyelonephritis with multiple scars, destruction of renal parenchyma, and slimy pus secondary to prostatic obstruction of long duration There was an abscess of the right psoas muscle, extending to the muscle origin at the lumbar spine, distinctly separate from the right kidney and ureter and extending inferiorly to the hip joint, greater and lesser trochanters, and the adductor region of the thigh. The abscess measured 38 by 7 by 6 cm The old fracture was ununited The cartilaginous surface of the head was irregularly eroded and covered with much purulent material Postmortem cultures of the abscess and renal pelves produced the same organism as antemortem cultures

Comment

This patient probably developed his septic process in the right hip region at some time after his early postoperative period He undoubtedly had a latent chronic pyelonephritis with recurrent exacerbations and occasional bacteremia The injured and operated hip was a locus minoris resistentiae where the metastasizing organism could create an active low-grade infection The low virulence of the organism and the resistance of the host due to prolonged urinary infection with the same organism allowed the infectious process to develop gradually, probably over a period of months or years The same factors also are assumed to have modified an organism which was originally a typical E coli The patient did not seek medical care until his last hospital admission when progressive renal destruction with uremia allowed his other disease process to develop more rapidly and become acutely symptomatic

At his last admission, the renal changes were irreversible Streptomycin could not be used Blood donors were unobtainable Incision and drainage of the abscess and urologic treatment were too late by months or years

Summary

A case of coxitis due to E coli is reported with autopsy findings and discussion of course and probable mechanism of the disease process

Laboratory Studies —The initial laboratory studies revealed erythrocytes 5,190,000, hemoglobin 15 1 Gm., leukocytes 8,400, with 70 per cent neutrophils, 27 per cent lymphocytes, 2 5 per cent monocytes, blood sugar 130 mg per cent, and urea nitrogen 18 mg per cent Voided urine showed specific gravity of 1 020, a trace of albumin, and occasional red and white cells per high powered field The spinal fluid was cloudy and contained 5,000 leukocytes with 90 per cent polymorphonuclears Gram-negative, intracellular diplococci were seen on direct smear, a culture later revealed them to be meningococci The spinal fluid sugar was 20 mg per cent On the second day of admission the white count was 29,100 with 76 5 per cent neutrophils and 22 per cent lymphocytes, 1 per cent monocytes, and 0 5 per cent basophils A catheterized urine specimen showed a specific gravity of 1 017, albumin 2 plus, occasional red and white cells per high powered field, and 3 to 4 finely granular and hyaline casts per high powered field The urine culture was negative A blood culture, not obtained until after chemotherapy was started, was sterile

Treatment —The patient was started on penicillin, 50,000 units intramuscularly every three hours and also received 4 5 Gm of sodium sulfadiazine intravenously, as well as adequate amounts of intravenous saline and sodium lactate solution. The penicillin was continued through the eighth day, and the sulfadiazine was continued orally for thirteen days, a dosage of 0 5 Gm every four hours becoming sufficient to maintain an average blood level of 8 mg per cent During the first twenty-four hours the patient received a total of 50 cc of adrenal cortical extract intravenously, during the same time intravenous fluids were administered almost constantly Sufficient fluid intake was accomplished orally after forty-eight hours, and the urinary output was never below 2,000 cc per twenty-four hours during the first ten days of therapy and remained normal thereafter

Course —The patient's blood pressure remained unobtainable for twelve hours after admission but gradually rose to normal in the next twenty-four hours The temperature fell to 100 F in the first twenty-four hours and then fluctuated between 99 and 101 F for two weeks, finally remaining consistently normal during the third week and thereafter For the first seventy-two hours the patient was restless and intermittently irrational. In lucid intervals she complained of severe headaches, generalized aching, and hyperesthesia throughout the body Oxygen was necessary to combat cyanosis from the third through the fifth day Signs of moderate pulmonary congestion appeared on the second day, associated with dyspnea, cough, and occasional blood-tinged sputum which contained only a few nonpathogenic organisms A chest x-ray on the fifth day showed moderate passive congestion

only The lungs became free of rales on the sixth day, and the respiratory rate was normal thereafter A systolic, apical murmur was first heard on the seventh day and remained for ten days At no time did signs of pericarditis develop An electrocardiogram on the eighth day showed slight right axis deviation and low but upright T waves in all leads

Herpes labialis developed on the fifth day and was quite extensive and troublesome for several weeks On the ninth day a few soft, tender nodules were noted on the extensor surfaces of the arms and legs More nodules appeared in the next two days involving the extremities chiefly, but also present over the breasts They were red, firm, very tender intracutaneous nodules varying from 1 to 3 cm in diameter They gradually subsided in the next week. Their appearance coincided with painful but not swollen ankle, knee, elbow and wrist joints The gradual disappearance of the nodules coincided with the beginning of a steadily normal temperature on the fifteenth day of the illness All joint symptoms had disappeared by the twenty-fifth day At no time was there any joint swelling The patient had not received any serum therapy The patient first complained of deafness and vertigo on the fifth day, and these symptoms persisted for three or four weeks Examination one month after the onset of her illness revealed only slight perception deafness bilaterally Three weeks later, the hearing was perfectly normal

A follow-up examination two months after the onset of the illness revealed an asymptomatic, healthy appearing woman The skin was entirely clear except for a small, subsiding remnant of herpes on the lower lip The blood pressure was 126/82, and complete physical examination was entirely normal. An electrocardiogram at this time revealed slight right axis deviation, a broad and notched P_2, P-R interval of 0 18 second, inversion of T_1 and T_2, a small C_3, and a low R_4 Blood count and urine analysis were normal A repeat electrocardiogram two months later was normal and similar in every respect to a routine tracing which had been taken a year prior to this particular illness Three years after this illness, the patient reported continuing excellent health.

Comment

The cause of circulatory failure in this syndrome has been assumed to be due mainly to acute adrenal insufficiency Since it has been established that the plasma volume is decreased in Addisonian crisis (adrenal insufficiency), a similar mechanism might be expected to account for the shock in the Waterhouse-Friderichsen syndrome [8] However, Kinsman *et al* reported three cases in none of which was there hemoconcentration characteristic of decreased plasma volume.[4] Ebert and Stead, studying cir tory failure occurring in cases of acute sepsis, f normal hematocrit and plasma volume va They concluded that the circulatory failure in cases does not have the same mechanism as of hemorrhage or traumatic shock because plasma volume is not decreased It is prol *that the circulatory failure in acute infectio* produced by failure of the entire cardiovas system through widespread damage by the infec Supporting this view is the study of cutaneou sions in acute meningococcemia by Hill and Ki who state that the fundamental pathologic le in the skin is diffuse vascular damage and that widespread vascular change is also found throug the serous surfaces and in other organs of the bo

It is, therefore, probable that the circula collapse in acute sepsis is due primarily to a w spread injury of many tissues, in particular, t of the cardiovascular system. The toxic effec infection produce disturbances in cell metabo throughout the body, and the circulatory failu secondary to the general failure of metabol Improvement in the circulation occurs when infection is brought under control

The recognition that this formerly fatal clu syndrome may now be reversible with the ad of chemotherapy places a premium on prompt d nosis and the institution of antibacterial therap

Summary

1 A recovered case presenting the charac istics of the Waterhouse-Friderichsen syndrom described

2 Attention is called to the possible mechan of the circulatory failure in this syndrome and potential reversibility with prompt treatment

TREAT VASCULAR DISEASES WITH HISTAMINE PREPARATION

Favorable results in treating patients for two types of vascular disease with injections of histamine in wax and sesame oil are reported by Drs S Feldman and J M Linder and I J Greenblatt, Ph D, of Brooklyn, in the September 24 *J.A.M.A*

The preparation was used for 30 patients with arteriosclerosis obliterans, for 41 patients with diabetes and arteriosclerosis obliterans, and for 13 patients with Buerger's disease Nine patients we treated for miscellaneous disorders, including va cose ulcers and fractures of the legs

Of 72 patients with lameness, 41 showed defini improvement, *the doctors say After the patien* had received a course of the histamine preparatio complete cessation of pain was observed in instances

ELECTROCARDIOGRAPHIC CHANGES IN MALARIA

IRVING GREENFIELD, M D , F A C P , Woodmere, New York

ALTHOUGH malaria has been considered a systemic disease, observations of the cardiac complications of this disease are sparse. From a review of the literature, it is evident that considerable controversy exists as to whether or not the heart is affected adversely by the malarial parasite Pathologists have observed abnormalities in the vessels of the myocardium Ewing observed capillaries in the myocardium distended with young parasites and pigmented cells.[1] Dudgeon and Clarke and Merkel recorded sudden death from cardiac failure and found degenerative changes in the myocardium, as well as infarcts in the myocardium.[2,3] The latter suggested that the condition behaved like any other form of coronary artery occlusion clinically Rojas and Deza observed thrombi made up of destroyed erythrocytes and parasites in various stages of evolution in the capillaries of the myocardium.[4] After recording the electrocardiographic changes present prior to the institution of therapy, they observed a favorable response in most of the cases soon after treatment was started Sprague studied the electrocardiograms in a series of 50 patients with recurrent malaria and observed no abnormalities in the tracings which could not be considered either within the normal variants or of nonspecific import [5] In a previous communication, attention was called to the case of a twenty-two-year-old marine, who, following three proved attacks of malignant tertian malaria, developed quintigeminal rhythm and heart block [6]

In view of the fact that pathologists have observed abnormalities in the vessels of the myocardium as well as in the myocardium itself and in view of the controversy which exists among clinicians concerning the effects of malaria of the heart, the occurrence of precordial discomfort, together with electrocardiographic changes following an attack of vivax malaria, is considered sufficiently unusual to warrant the following case report

Case Report

A thirty-year-old white man who had served in the tropics of the South Pacific for two years gave the following history He had dengue fever in 1944. Shortly thereafter, he had his first attack of malaria. His second attack was in April, 1946, after he had discontinued suppressive therapy (atabrine) During this episode Plasmodium vivax was again identified in the blood smear The attack was treated with atabrine, and recovery was uneventful. Routine examination in July, 1948, revealed no abnormalities. The electrocardiogram including, in addition to the standard limb leads, CF_2, CF_4, and CF_6, is reproduced (Fig 1A) In brief, it is a normal electrocardiogram, save for some splintering of the main complex lead 3

In August, 1948, following a period of intense excitement, he had a chill which lasted about twenty minutes, followed by fever and sweat The physical examination at this time was entirely normal The spleen was not enlarged The heart tones were normal. The systolic blood pressure in mm. of mercury was 110, and the diastolic was 70 Blood smears revealed the presence of Plasmodium vivax Atabrine was again given On the third day the patient developed precordial lancinating pains, felt chilly, broke out into a sweat, and complained of weakness He had no chill, and there was no elevation of temperature. There was no significant drop in his blood pressure Malarial parasites were again present in the blood smear There was no significant change in the leukocyte count. An electrocardiogram taken at this time revealed depressions of the T wave in leads 1, 2, CF_2, CF_4, and CF_6 (Fig 1B) The entire contour of the complex in lead 3 had changed. R was small, S was the predominant deflection, ST was isopotential, and T was inverted With bed rest the symptoms subsided After six weeks the electrocardiogram (Fig 1C) had returned to the control (Fig 1A) pattern The hemograms are recorded in Table 1

The parasites were seen in the smear on four occasions as noted (Table 1) during August, 1948. No parasites were seen in the smears examined after August 26, 1948. At no time was a pericardial friction rub heard

A teleoroentgenogram taken on the same day as the electrocardiogram was normal (Fig 2)

Comment

There are several points of interest in this case presentation The onset of the clinical picture, which the patient recognized as identical with those symptoms which he had while in the tropics, as well

TABLE 1.—LABORATORY DATA

1948	Aug. 12	Aug 14	Aug. 16	Aug. 26	Sept 17	Sept 23
Hemoglobin	114%	118%		108%		103%
Red blood cells	5 000 000	4 900 000	4 810 000	5 000 000	4 940 000	4 910 000
White blood cells	7 450	8 300	9 450	6 900	10 100	8 350
Polymorphonuclears	56	53	53	54	55	48
Lymphocytes	32	41	38	39	39	43
Monocytes	7	1	2	3	2	2
Eosinophils	2	2	2	2	1	3
Juvenile cells			1			1
Stab forms	3	3	4	2	3	3
Basophilic stippling	++	+	+	+	0	0
Parasites	++	+	+	+	0	0

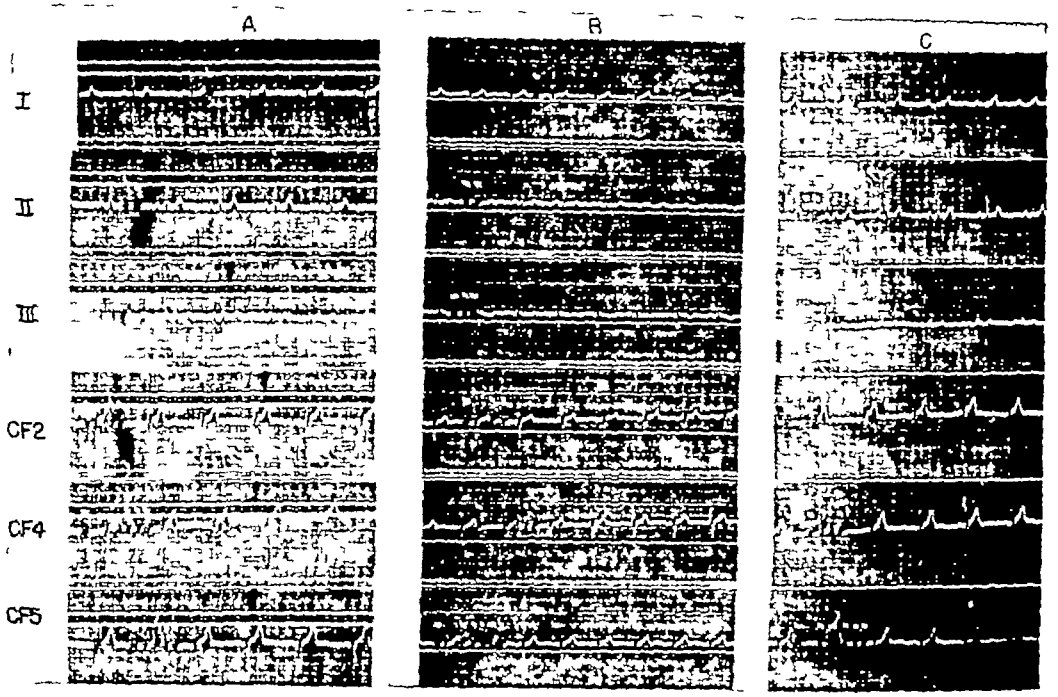

FIG 1 Electrocardiograms taken as indicated T waves in all leads of B are of lower voltage than they were in control (A) In lead 3, the T wave is inverted (C), taken six weeks after (B), shows a return of the T waves to the control amplitude

as those which he had soon after he discontinued suppressive therapy, was striking The patient was involved with labor-management problems in a large plant After five days of excitement, the chill appeared, and the smear was positive for *Plasmodium vivax*. There was no exposure to malaria other than that noted while the patient was on tropical service

On the third day after the onset of the clinical symptoms in the recent episode, pain in the precordium appeared, followed by chilly sensation, sweat, and weakness At this time the white cell count was elevated to 9,450 cells There was no significant change in the differential count The number of cells containing parasites and the number of cells with basophilic stippling had diminished The electrocardiographic changes involved the T waves in all the leads The contour of the main complex in lead 3 was changed completely, and T_3 was inverted After a period of bed rest the configuration of the electrocardiogram reverted to the control pattern

In order to rule out the atabrine as the causative factor, the patient was given therapeutic dosage of this chemical following the lapse of an adequate interval Electrocardiograms were taken to ascertain whether that chemical agent was responsible for the electrocardiographic changes noted. They differed in no way from that recorded in Fig 1C, and

Summary

1 A case of malaria with electrocardiographic changes is recorded

2 Since the electrocardiographic changes noted

FIG 2 The teleoroentgenogram, taken on October 17, 1948, is essentially normal

were not reproduced following a second administration of atabrine in the absence of malaria, it is reasonable to eliminate atabrine as a causative agent

3 In the absence of any other explanation for the symptomatology and the electrocardiographic changes recorded, it is reasonable to assume that the heart muscle changes resulted from malarial thrombi in the myocardium

DEATH IN A CASE OF BRONCHIAL ASTHMA TREATED SUCCESSIVELY WITH INTRAVENOUS PROCAINE AND SODIUM AMYTAL

Maxwell L Gelfand, M D , Monroe H Mufson, M D , and Walter P Richman, M D
New York City

(From the Fourth Medical Division, Bellevue Hospital, and New York University College of Medicine)

RECENT years have witnessed a great enthusiasm for the use of intravenous procaine in many fields of medicine The fact that the liver can rapidly detoxify procaine has led many observers to feel safe in employing relatively large amounts of this drug Although toxic reactions from intravenous procaine have been noted, many thousands of such injections have been given without any serious mishap Recently a fatality following the successive use of procaine and sodium amytal intravenously in a chronic asthmatic was encountered and is herewith reported

Case Report

A. H , a fifty-four-year-old man, entered Bellevue Hospital on November 12, 1948, complaining of marked dyspnea, orthopnea, paroxysmal episodes of cough, and weakness of one week duration He visited his local physician on the morning of November 12 and was given 0 5 cc of adrenalin (1 1,000) without any benefit He was then referred to Bellevue Hospital where, in the emergency room, he received 20 cc of aminophylline intravenously There was no alleviation of his asthma, and so he was admitted to the ward for further study

The past history disclosed that in August, 1943, the patient sustained multiple rib fractures with depression of the sternum complicated by a right middle lobe pneumonia Several months after this injury, bronchial asthma of the perennial type developed There was no family allergic history Skin tests performed at the allergy clinic revealed positive reactions to many inhalants and foods but no evidence of infection It was also noted that the fumes emanating from the taxi which he operated initiated an attack In August, 1948, he spent three weeks at Bellevue Hospital for an episode of intractable asthma, with recovery

Physical examination revealed a well-developed and well-nourished adult white man in acute respiratory distress with slight cyanosis and marked apprehension His pupils were equal and regular and reacted to light and accommodation The external ocular movements were normal, and the fundi failed to disclose any evidence of hemorrhages, exudates, or papilledema His nose and throat were normal. There were no masses in the neck, and the thyroid was not palpable His chest was emphysematous and symmetric Cardiac dullness was not enlarged, and the heart sounds were distant The rhythm was regular, and there were no murmurs or thrills. The rate was rapid, and the blood pressure was 160/100 The lungs revealed numerous inspiratory and expiratory wheezes with many sibilant and sonorous rales throughout There were no palpable masses or organ edges felt on abdominal examination Rectal examination revealed a small prostate with no masses The extremities disclosed no evidence of edema or inflammation Homan's sign was negative

Urinalysis, hematologic study, and blood chemistry findings failed to reveal any abnormal findings The venous pressure was 120 mm. of water, and the decholin circulation time was eight seconds.

Procaine hydrochloride solution, 0 2 per cent, was prepared by dissolving 1 Gm. of procaine in 500 cc of normal physiologic saline, and an intravenous infusion was begun at 4 00 P.M. on November 12 1948, at the rate of 45 drops per minute The blood pressure reading, pulse rate, respiratory rate, and subjective and objective signs were recorded every fifteen minutes It was noted that the pulse remained between 120 to 140, and the original blood pressure of 160/100 dropped to 138/78 at 6 45 P M and then rose again to 170/110 at 7 00 P M and at 7 15 P.M. The patient felt considerably relaxed and appeared comfortable with decrease of cyanosis and dyspnea. However, at 7 15 P.M., after 250 cc of the infusion had been given, the patient complained of dizziness and a metallic taste in the mouth He became markedly agitated, excited threw himself about jumped out of bed, and it

required four men to put him back At this time his pulse rate was 160, respiratory rate 22, and blood pressure 170/110 The infusion was immediately withdrawn, and, while he was held down, 0 5 Gm. of sodium amytal was given intravenously Within a few minutes the patient calmed down somewhat and dozed slightly Suddenly he again attempted to jump out of bed, became markedly agitated, cyanotic, breathed heavily, and expired

Comment

The failure to respond to the conventional therapy for bronchial asthma, such as oxygen, adrenalin, and intravenous aminophylline, always causes considerable concern and leads one to search for another method of treatment The use of intravenous procaine for bronchial asthma is not without precedent The French medical literature is filled with favorable reports concerning the beneficial effects obtained with intravenous procaine in chronic bronchial asthma However, in this country, there is only an occasional mention of its use State and Wangensteen treated 27 cases with intravenous procaine without any untoward reactions, and of this group only one was a case of bronchial asthma [1] No benefit resulted in the latter patient from such therapy, but in their other instances of hypersensitive states considerable amelioration of symptoms occurred In the cases treated by Rovenstine at Bellevue Hospital, there were several patients with bronchial asthma who received intravenous procaine without success [2] Appelbaum, Abraham, and Sinton, employing the technic suggested by State and Wangensteen, obtained an excellent result in a case of serum sickness following tetanus antitoxin [3] Delayed reactions to penicillin were successfully treated by Dressler and Dwork and Rossellini and Van Rooy [4,5] Thus it was thought worth while to attempt this method of therapy for this patient, who presented symptoms of status asthmaticus uncontrolled by the usual regime

Procaine owes its therapeutic success to a multiplicity of actions of which the major one is the ability to paralyze the sympathetic nerves, producing smooth muscle relaxation and vasodilatation Harvey has shown that procaine has a curare-like action in the myoneural junction, reducing the amount of acetylcholine produced and neutralizing the acetylcholine that is liberated [6] It may also exert its effect by direct action on the endings of the sensory nerve fibers, by antagonizing histamine or histamine-like substances, and by potentiating epinephrine secretion

The dosage recommended is 1 Gm. of procaine dissolved in 500 or 1,000 cc of either glucose or saline to be given by the infusion method at a rate ranging between 40 to 50 drops per minute The amount and the rate of administration employed in this case is in conformity with the accepted technic

The performance of a skin test prior to the use of the drug to determine hypersensitivity, as has been suggested by many observers, is a useless procedure. Positive direct skin reactions of the immediate wheal type are rarely observed in instances of drug allergy, hence its omission here

Benign deleterious effects noted during intravenous procaine therapy consist of a sensation of warmth throughout the entire body occurring about five minutes after the infusion has begun, a metallic taste in the mouth, lacrimation, nausea, giddiness, and sluggish speech. Serious consequences are marked apprehension, excitability, convulsions, and signs of bronchial constriction The dosage and the rate of administration are governing factors in determining the degree and severity of reaction However, it is agreed that in order to obtain a maximum therapeutic result it is necessary to secure a mild toxic response Oftentimes the line of demarcation between a harmless and grave outcome cannot be accurately measured

The improvement of the bronchial asthma noticed after the onset of intravenous procaine suggested a successful response to the drug After half the solution entered the blood stream, symptoms of nervous system irritability appeared requiring the use of sodium amytal by vein The barbiturates of either moderate or short duration action are the accepted antidote for the toxic nervous system reaction to intravenous procaine Occasionally, accidental poisoning may follow the use of intravenous amytal, and death results from paralysis of the respiratory center

The terminal episode in this patient was one of marked cerebral anoxia It is difficult to identify the exact cause of this mechanism for there are three factors to be considered First is the bronchial asthma per se, which can produce an anoxic type of anoxia Second is the intravenous procaine, which may have increased the bronchoconstriction already present and also acted on the higher centers, creating anoxia Third is the sodium amytal with its potential hazard of depression of the respiratory center resulting in anoxia Death may have been the result of any of the above components or the cumulative effect of all three

Summary

1 A case of bronchial asthma that did not respond to epinephrine and aminophylline is herewith presented

2 An infusion of 1 Gm of procaine in 500 cc of saline was given at a rate of 40 to 45 drops per minute for the relief of the asthmatic state

3 After half the dose was administered a marked irritability and restlessness was noted

4 Sodium amytal was then given intravenously to counteract the marked restlessness and excitability, and shortly thereafter death occurred

5 The terminal picture closely resembled cerebral anoxia, and the probable factors responsible for such anoxia in this case are mentioned

THE MASTER "2-STEP" EXERCISE TEST IN THE DIFFERENTIAL DIAGNOSIS OF CORONARY ARTERY DISEASE

SIDNEY STORCH, M D , LEON PORDY, M D , and JOSEPH KOLKER, M D , New York City

(*From the Cardiographic Department of Mt Sinai Hospital*)

THE Master "2-step" exercise test and the anoxemia test have both been employed with greater frequency in recent years as important aids in the objective diagnosis of coronary artery disease when the resting electrocardiogram is normal.[1-3] The case of a man sixty years of age with gastrointestinal bleeding and coronary disease is described because of the diagnostic problem he presented. The differential diagnosis rested between duodenal ulcer, cerebral lesion, and coronary disease, with the ultimate solution arrived at by use of the Master "2-step" test The results of the latter were confirmed nine months later by an attack of spontaneous angina followed by myocardial infarction due to coronary occlusion

Case Report

The patient, B N , was a sixty-year-old white man whose relevant past history was as follows He was first admitted to the Mount Sinai Hospital, New York City, on March 1, 1946, with the chief complaint of gnawing epigastric pain with radiation to the mid back region This had persisted for three weeks prior to his admission to the hospital He gave a history of epigastric pain and gastrointestinal bleeding for several years for which he was hospitalized twice in the city hospitals of New York. A diagnosis of bleeding duodenal ulcer was made Three weeks prior to this Mount Sinai Hospital admission he experienced severe gnawing epigastric pains, not relieved by food or alkali. He entered the hospital with extreme epigastric pain with mid back radiation. The laboratory studies at this time showed blood urea, blood sugar, total proteins, and urine analysis all normal, blood Wassermann and Kahn negative, hemoglobin 103 per cent, white blood cells 3,800 with normal differential count, sedimentation rate 20 mm. per hour (Westergren), stool guaiac negative, blood hematocrit 48 per cent, Rehfuss test showed free hydrochloric acid. The patient was discharged as a case of simple duodenal ulcer on March 22, 1946

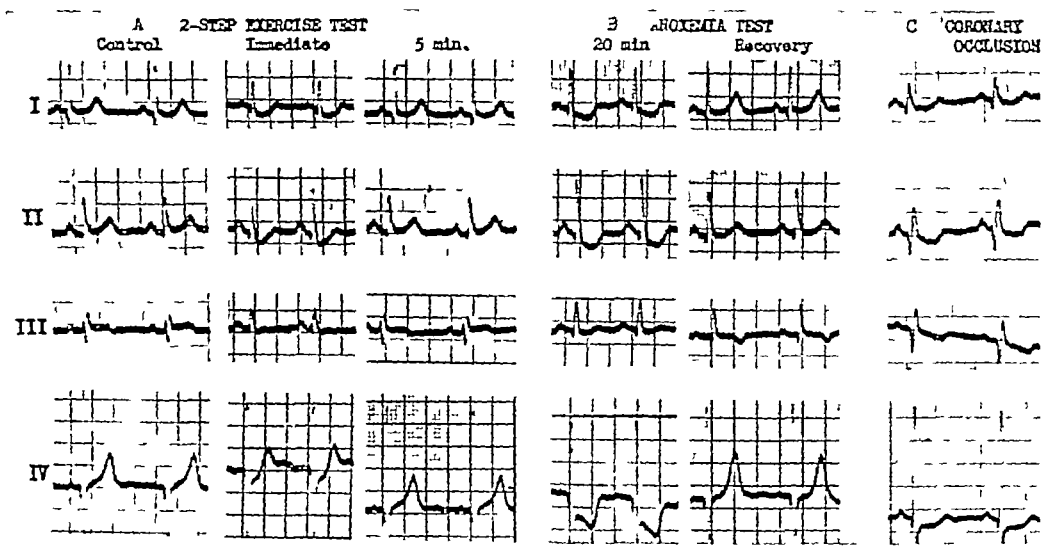

FIG 1 B N , a patient with acute coronary insufficiency and pressure heaviness over the chest radiating to back, not related to effort, often accompanied by syncope Physical examination, including neurologic, negative

(A) Normal electrocardiogram at rest The "2-step" exercise test taken on February 7, 1947, positive for acute coronary insufficiency, showed definite RS-T depressions and T-wave inversions

(B) Ten per cent anoxemia test, taken on February 20, 1947, was also positive for acute coronary insufficiency

(C) Electrocardiogram taken on January 5, 1948, showed large Q_3 and Q_4 indicative of previous coronary occlusion with posterior wall infarction, the RS-T segment depression in lead IV accompanied the clinical episode of acute coronary insufficiency

The patient was seen frequently in the outpatient department and had no unusual complaints until January 24, 1947, five days prior to his second Mount Sinai Hospital admission on January 29, 1947, when he began to experience sudden attacks of syncope associated with pressure over the lower portion of the chest or upper abdomen which radiated to the mid back. The pressure was not related to effort There was also shortness of breath on exertion Physical examination was normal. The diagnosis was considered to lie between a cerebral lesion (because of the syncope) and a bleeding duodenal ulcer Coronary disease was not suspected since the resting electrocardiogram was normal. No evidence of bleeding could be discovered, and the stool examination was negative The neurologic examination was normal The patient was referred to the cardiographic department for consultation Here coronary artery disease was suspected, and the Master "2-step" test was performed Figure 1A shows the results of this test Distinct RS-T depressions and T wave inversions appeared in leads I, II, and IV, and a diagnosis of coronary artery sclerosis was made This was confirmed by the 10 per cent oxygen test which disclosed conspicuous depressions of the RS-T segment in leads I, II, and IV (Fig 1B) Subsequent events further established the specificity of the "2-step" test

Nine months later, the patient developed a classic anginal syndrome, i e , substernal pressure on effort or excitement, and he suffered an acute coronary occlusion with infarction involving the posterior wall of the left ventricle The electrocardiogram showed a deep Q_2Q_3 pattern

On January 5, 1948, while attending the cardiac outpatient department, the patient had a sudden attack of substernal oppression and drop in blood pressure from 140/92 to 112/90, accompanied by tachycardia, weak pulse, cold sweat, and pallor, and the patient was admitted to the ward in partial shock. A diagnosis of coronary artery sclerosis with insufficiency was made (Fig 1C) Here again the laboratory showed normal hemoglobin with stools negative for blood

Summary

1 This case demonstrates the value of the Master "2-step" test in substantiating the diagnosis of coronary artery disease in a patient whose previous history was quite misleading

2 The "2-step" test was the only positive finding and was positive nine months before the patient suffered an attack of acute coronary insufficiency

"DOCTOR JONES SAYS"—

In Arkansas, one time, we visited a cotton plantation One of the cabins had a piano on the porch and we asked the boss, "How come?" They'd bought it on the installment plan, he said, and when it came there wasn't room for it inside It wouldn't go through the door, anyway, so it was the best they could do It's something like that, I guess, undertaking to tell the psychoanalysis story in three small installments

The analyst—we haven't said much about him He's the mainspring that makes the analysis "tick." The success of the operation depends largely on his personality, experience, and skill—and ability to pick promising cases Oh, sure, there's women analysts Why not?

What folks are likely to be benefited by analysis it'd make a long list People with troublesome neuroses—they're the ones that need it most, so they usually give 'em priority Many people in mental institutions might be helped by it, but it takes too much time and individual attention to be practicable, as a general proposition But lots of intelligent, serious-minded people, not too old, that aren't satisfied with their personalities and reactions would be better for it The late Rabbi Liebman, that wrote *Peace of Mind*, had been analyzed, so I'm told. More and more doctors are going into it. When they understand 'emselves they're better able to understand their patients and their reactions

The results—well, they vary, naturally The analysts try to weed out the poor prospects, even so, some can't make the grade The ones that're successful (probably the majority) neuroses are relieved and "normal" folks are better able to deal with the realities of life The way it changes people—that part of it is a story by itself

How do I know these things? Well, I'll tell you it's like the burdocks my Sealyham had on him when he'd been out in the brush back of the barn He'd picked 'em up going through it —*Paul B Brooks, M.D , October 24, 1949*

ACUTE MYOCARDIAL INFARCTION IN A SIXTEEN-YEAR-OLD BOY

ALBERT H DOUGLAS, M D , F A C P , and LEON MARIENBERG, M D , Jamaica, New York

(From the Queens General Hospital and The Jewish Hospital of Brooklyn)

ACUTE myocardial infarction in childhood is an uncommon event However is our case illustrates it can occur, and it must be considered in the differential diagnosis of chest pain in the young

Case Report

R. D , a sixteen-year-old boy, developed mild pain in the sternal region on June 24, 1948. This pain subsided in a few moments and was disregarded. Five days later, the patient awoke with severe pain in the same area. The pain was attributed to the effort involved in racing up a car the day before It was described as sharp and bore no relation to respiration, position change or swallowing It did not radiate and lasted all day There were no associated symptoms.

The past history included mumps at five, measles and whooping cough at six. At eleven the patient had a high fever of unknown cause, not associated with joint pains, that lasted two weeks. At the age of fourteen he was treated for obesity with one grain Proloid daily for a period of five months His weight fell from 220 to 180 pounds The basal metabolic rate is said to have been normal at this time From November, 1947, to March, 1948, the patient was given 25,000 units of Vitamin A twice a day as treatment for acne vulgaris.

The family history was significant only in the fact that the patient's father had a coronary artery thrombosis at the age of forty-eight

Physical examination done on July 1, 1948 two days after the onset of the acute illness, revealed a well-developed, slightly obese boy of sixteen in no apparent distress He was 5 feet 8½ inches tall and weighed 180 pounds There were no positive findings except for acne vulgaris of face and chest and a faint systolic, blowing murmur localized over the pulmonic area and audible during expiration only The blood pressure was 120 70 An electrocardiogram showed a T_1 type of pattern sugges-

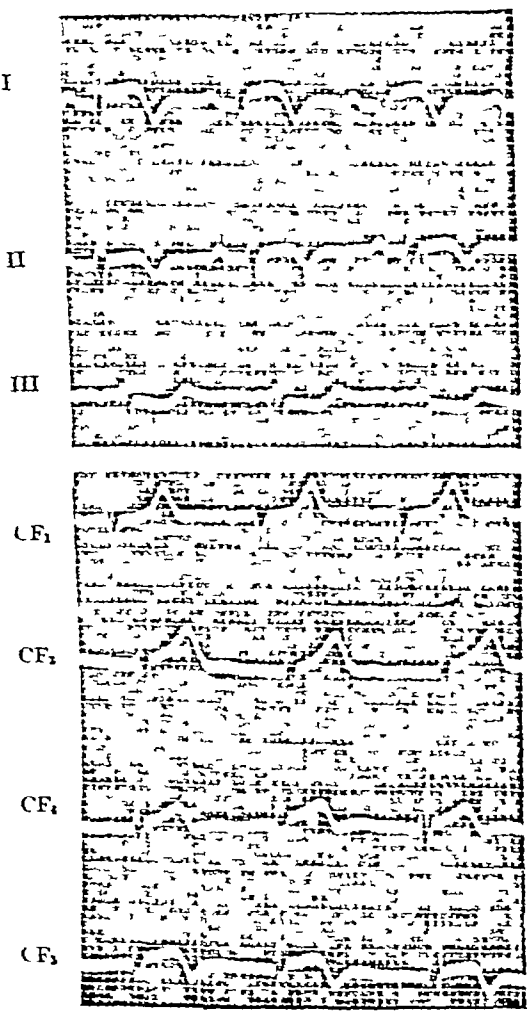

FIG 1. Electrocardiogram taken on July 1, 1948.

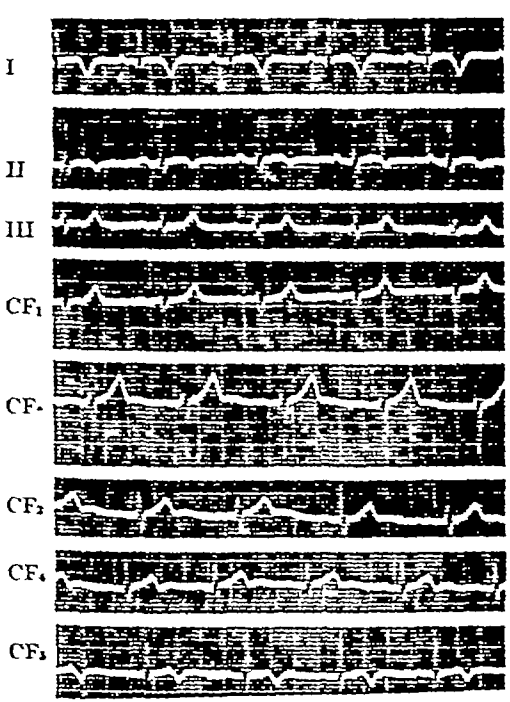

FIG 2. Electrocardiogram taken on July 28, 1948.

The patient was seen frequently in the outpatient department and had no unusual complaints until January 24, 1947, five days prior to his second Mount Sinai Hospital admission on January 29, 1947, when he began to experience sudden attacks of syncope associated with pressure over the lower portion of the chest or upper abdomen which radiated to the mid back. The pressure was not related to effort There was also shortness of breath on exertion Physical examination was normal The diagnosis was considered to lie between a cerebral lesion (because of the syncope) and a bleeding duodenal ulcer Coronary disease was not suspected since the resting electrocardiogram was normal No evidence of bleeding could be discovered, and the stool examination was negative The neurologic examination was normal The patient was referred to the cardiographic department for consultation Here coronary artery disease was suspected, and the Master "2-step" test was performed Figure 1A shows the results of this test Distinct RS-T depressions and T wave inversions appeared in leads I, II, and IV, and a diagnosis of coronary artery sclerosis was made This was confirmed by the 10 per cent oxygen test which disclosed conspicuous depressions of the RS-T segment in leads I, II, and IV (Fig 1B) Subsequent events further established the specificity of the "2-step" test

Nine months later, the patient developed a classic anginal syndrome, i e , substernal pressure on effort or excitement, and he suffered an acute coronary occlusion with infarction involving the posterior wall of the left ventricle The electrocardiogram showed a deep Q_3 pattern

On January 5, 1948, while attending the cardiac outpatient department, the patient had a sudden attack of substernal oppression and drop in blood pressure from 140/92 to 112/90, accompanied by tachycardia, weak pulse, cold sweat, and pallor, and the patient was admitted to the ward in partial shock. A diagnosis of coronary artery sclerosis with insufficiency was made (Fig 1C) Here again the laboratory showed normal hemoglobin with stools negative for blood

Summary

1 This case demonstrates the value of the Master "2-step" test in substantiating the diagnosis of coronary artery disease in a patient whose previous history was quite misleading

2 The "2-step" test was the only positive finding and was positive nine months before the patient suffered an attack of acute coronary insufficiency

"DOCTOR JONES SAYS"—

In Arkansas, one time, we visited a cotton plantation One of the cabins had a piano on the porch and we asked the boss, "How come?" They'd bought it on the installment plan, he said, and when it came there wasn't room for it inside It wouldn't go through the door, anyway, so it was the best they could do It's something like that, I guess, undertaking to tell the psychoanalysis story in three small installments

The analyst—we haven't said much about him. He's the mainspring that makes the analysis "tick" The success of the operation depends largely on his personality, experience, and skill—and ability to pick promising cases Oh, sure, there's women analysts Why not?

What folks are likely to be benefited by analysis it'd make a long list People with troublesome neuroses—they're the ones that need it most, so they usually give 'em priority Many people in mental institutions might be helped by it, but it takes too much time and individual attention to be practicable, as a general proposition But lots of intelligent, serious-minded people, not too old, that aren't satisfied with their personalities and reactions would be better for it The late Rabbi Liebman, that wrote *Peace of Mind*, had been analyzed, so I'm told More and more doctors are going into it When they understand 'emselves they're better able to understand their patients and their reactions

The results—well, they vary, naturally The analysts try to weed out the poor prospects, even so some can't make the grade The ones that're successful (probably the majority) neuroses are relieved and "normal" folks are better able to deal with the realities of life The way it changes people—that part of it is a story by itself

How do I know these things? Well, I'll tell you it's like the burdocks my Scalyham had on him when he'd been out in the brush back of the barn He'd picked 'em up going through it —*Paul B Brooks, M D , October 24, 1949*

CATHETER FOUND IN PERITONEAL CAVITY FOLLOWING ABORTION

BERNARD J FICARRA, M D , Brooklyn, New York

(From the Department of Surgery, Holy Family Hospital)

THE evil effects of criminal abortion, on both the moral and physical levels, are universally recognized Attention is focused on this topic when unwanted publicity is given to it in the daily press or when an unusual condition associated with an abortion demands special consideration This latter situation has been a recent experience which is believed worthy of recording

Case Report

The patient, Mrs A I , a twenty-five-year-old housewife, was seen for the first time on October 9, 1948 At 8 30 P M of that day, she was admitted to the hospital as an emergency patient On admission she presented the following history Two weeks prior to admission she was treated at home by her family physician for "colic" Twenty hours before her hospital admission she had a recurrence of this "colic" which became quite severe Her family physician was again consulted At this time he stated that she might be developing acute appendicitis Later that evening, October 9, 1948, the same physician stated that she had appendicitis and should be hospitalized.

On examination at the time of admission, the patient complained of moderate abdominal pain She was not dehydrated and had not vomited The significant findings were demonstrated on abdominal examination There was marked bilateral lower abdominal tenderness with rebound. Vaginal examination revealed a pelvic mass about 4 cm. in diameter attached to the left adnexa This mass was tender to palpation and imitated much pain on motion The diagnostic impression at that time was a tubal abscess for which conservative treatment was instituted

The laboratory report on the day of admission indicated leukocytosis (14,500 cells) and a very rapid sedimentation rate Conservative therapy was effective, and the patient was discharged two weeks after her admission

Several weeks later she was readmitted to the hospital for elective surgery On November 9, 1948, an exploratory laparotomy was performed. The operative findings were not anticipated

A left tubal abscess was found attached to the fimbriated end of the fallopian tube Adherent to the abscess was a number 12 rubber catheter with 1 inch missing from the distal end This end of the catheter was imbedded in the abscess. The proximal two thirds of the catheter was firmly adherent to a section of ileum At one point the catheter completely encircled the ileum, constricted the intestine, and was so adherent to the serosa that it had to be dissected free with a scalpel (Fig 1)

Following operation the patient was questioned more thoroughly and presented the missing information in the true story of her illness In 1944, the patient was married She became pregnant and gave birth to a baby girl on December 25, 1944. Two years later she was pregnant again Having separated from her husband, she was in Florida awaiting a divorce While there, she visited a female nurse who inserted a rubber catheter vaginally on July 30, 1946 The nurse could not retrieve the catheter and cut the distal end so that it would not protrude from the vagina Three months after the nurse inserted the catheter, the patient expelled a three-month-old fetus Hemorrhage occurred on the next day She was hospitalized in Florida on the same day and passed the placenta the next day

In 1947 she was reconciled to her husband. She became pregnant again and on September 1, 1948, gave birth to a normal baby boy

FIG 1 Catheter and abscess removed at time of operation. Arrows indicate intestinal serosa adherent to catheter

Comment

The presentation of this case is unusual from several points of view First, a catheter inserted vaginally entered the uterus and finally came to rest in the peritoneal cavity where it became adherent to small intestine and formed a tubal abscess Second, the catheter became densely adherent to the ileum, was covered with serosa, and in one area completely encircled the intestine without causing an intestinal obstruction Third, a normal pregnancy and delivery occurred with this catheter still attached to the left tube and present in the peritoneal cavity

Up to the present time, the patient is well and has a normal menstrual cycle

tive of acute myocardial infarction with involvement of the anterolateral aspect of the ventricles by a lesion limited to the subendocardial layer (Fig 1)

The patient ran a low-grade fever to 100 F orally for three days Thereafter his temperature was normal The sedimentation rate was 38 mm in an hour on June 29, 1948 The blood cholesterol was 215 *Urinalysis was negative.* Re-examination on July 28, 1948, a month after the onset of the illness, revealed no change in physical findings The patient was asymptomatic and anxious to get out of bed His blood pressure was 140/50 An electrocardiogram showed return of the displaced S-T segment in leads 1 and 3 and CF_4 to an isoelectric level, sharp inversion of the T wave in leads 1, 2, CF_4, and CF_5 persisted The electrocardiographic patterns are typical of acute myocardial infarction.

Comment

Diabetes, hypertension, hypothyroidism, and *familial hypercholesterolemia* are common predisposing causes of atherosclerosis None were present in the case described However, the patient was obese, and this may have been significant French and Dock reported eighty cases of fatal coronary arteriosclerosis in young soldiers and found that 73 were overweight [1] Five of their cases were in the age group twenty to twenty-two years. Newman has also noted the good physical development and nourishment of young adults with coronary occlusion [2] He reported 50 cases in service personnel, including 22 in the age group twenty to thirty The literature includes a number of autopsy reports which describe coronary disease in children without mention of the nutritional state of the subjects.[3-6]

Summary

A case of acute myocardial infarction with recovery in a sixteen-year-old boy is reported. The possible relationship of obesity to coronary sclerosis in the young is illustrated by this case

DOCTORS FIND INHERITED TENDENCY TOWARD DISEASE OF CORONARY ARTERY

Existence of a hereditary tendency toward development of one type of hardening of the coronary artery is indicated by studies made by three New York doctors, David Adlersberg, Albert D Parets, and Ernst P Boas of Mount Sinai Hospital, reporting their findings in the September 24 *Journal of the American Medical Association*

The common factor for most patients with atherosclerosis of the coronary artery, a form of hardening characterized by fatty degeneration of tissue of the arterial walls, appears to be a hereditary disturbance of the body's metabolism of cholesterol, a fatlike substance found in all animal fats and oils The doctors investigated 201 persons belonging to families with xanthoma for large amounts of cholesterol in the blood, coronary artery disease, and other "stigmas" found in xanthoma.

Serum cholesterol was determined in 175 of these persons and found elevated in 122 Coronary artery disease was found in 80 patients of the entire group Serum cholesterol was determined in 66 of these 80 patients and found elevated in 57 Genetic analysis of the families supports the concept that this disturbance of cholesterol metabolism is inherited, the doctors point out.

These results were compared with those of a previous investigation in which 122 patients with disease of the coronary arteries were examined for elevated serum cholesterol and "stigmas" associated with it. Seventy-one had an excess of cholesterol in the blood In addition, 50 families of these 122 patients were studied In 15 families all or most children exhibited an excess of cholesterol in the blood, as did half of the children in nine other families.

"A hereditary disturbance of lipid metabolism is only one of the conditioning factors for the development of coronary artery disease," the doctors write "A disturbance of uric acid metabolism may play an associative role *It may well be that for persons* with a tendency toward hypercholesterolemia a 'normal' American diet contains sufficient fat and cholesterol to maintain the serum cholesterol levels at critical values which may hasten atheroma formation, whereas a low fat diet may exert a retarding effect on the pathologic process.

"The serum cholesterol of all relatively young patients affected with coronary atherosclerosis should be determined as the initial step in uncovering hypercholesterolemia in members of their immediate family Those whose cholesterol level is found to be elevated should be examined for latent cardiovascular disease and should be kept under permanent medical supervision"

In Chronic Hepatitis Hepatic Insufficiency...Cirrhosis

A Better Tasting Choline

The extremely pleasant citrus flavor of Solution Choline Gluconate C S C overcomes one of the greatest obstacles to prolonged choline therapy This preparation is exceptionally well tolerated and is readily taken in the prescribed dosage over the prolonged periods usually required in the treatment of chronic hepatic disorders

Higher Choline Content

Containing 61 7% choline gluconate or the equivalent of 25% choline base Solution Choline Gluconate C S C provides more choline than any other preparation available for clinical use *Adequate* dosage may be given for utmost therapeutic value This higher choline concentration is made possible by the high content of the choline gluconate salt

Outstanding Economy

In terms of choline equivalent, Solution Choline Gluconate C S C offers outstanding value to your patients This point is of utmost importance since the management of chronic hepatitis, hepatic insufficiency, and cirrhosis of the liver usually involves treatment extending over a period of several months

Solution Choline Gluconate C S C is available on prescription in 16 oz bottles Because of its economy, it is suggested that the original 16 oz bottle be prescribed

NECROLOGY

Joseph Henry Acton, M D , of Endicott, died suddenly on October 24 at his home from a heart attack at the age of fifty-one Dr Acton received his medical degree from McGill University College of Medicine in 1925 Before beginning his medical studies, Dr Acton had served with the British Royal Air Force in France during World War I He became one of the Allies' top war aces and was a member of the "Quiet Birdmen," an organization of the first fifty war aces

Dr Acton had been a member of the surgical staff of the Ideal Hospital of Endicott and belonged to the Broome County and New York State Medical Societies and the American Medical Association

L Franklin Anderson, M.D , of Buffalo, died on October 24 after a long illness at the age of sixty-seven Dr Anderson was graduated in 1907 from the University of Buffalo School of Medicine Before his retirement because of illness, Dr Anderson had been consulting anesthetist at Gowanda State Hospital in Helmuth and attending anesthetist at Lafayette General, Millard Fillmore, and Emergency Hospitals in Buffalo He was a member of the American Society of Anesthetists, the Erie County and New York State Medical Societies, and the American Medical Association

Frank Edwin Brundage, M.D , of Buffalo, died on October 25 at the age of sixty-eight Dr Brundage was graduated from the University of Buffalo School of Medicine in 1909 and had retired recently as chief medical officer of the Veterans Administration for western New York During World War II Dr Brundage served as a colonel in the Army Medical Corps for five years, including one year of foreign service in Algiers He was associate consulting pediatrician at Meyer Memorial Hospital in Buffalo Dr Brundage was a member of the Erie County and New York State Medical Societies and the American Medical Association

William John Cavanaugh, M.D , of Poughkeepsie, died on October 23 at his home after a long illness, at the age of seventy-five. Dr Cavanaugh was graduated from the Albany Medical College in 1899 and had retired in 1943 because of ill health He had opened a practice in Oneonta and then served at the Willard State Hospital, Willard, before joining the staff of the Hudson River State Hospital, Poughkeepsie, in 1901 Dr Cavanaugh was supervising psychiatrist when he retired in 1943

In May, Dr Cavanaugh was honored at the 1949 meeting of the Medical Society of the State of New York, in Buffalo, for his completion of fifty years in the practice of medicine. He also received an award from the Alumni Association of Albany Medical College in recognition of fifty years of meritorious service to humanity Dr Cavanaugh was a member of the American Psychiatric Association, the National Committee on Mental Hygiene, the Dutchess County and New York State Medical Societies, and the American Medical Association

Joseph Angelo Devlin, M.D , of New York City, died suddenly on November 4 of a heart attack at the age of sixty-five. Dr Devlin received his medical degree from the University of Maryland in 1906 and interned at St Francis Hospital in New York City He began his practice in 1910 Dr Devlin served as consulting obstetrician and gynecologist at Misericordia Hospital and as attending obstetrician and gynecologist at St Clare's Hospital, both in New York City He was also consulting surgeon to the New York City Police Department, executive medical officer of the Third Naval District, and medical officer of the 69th Regiment of the New York National Guard

Dr Devlin was a Fellow of the American College of Surgeons and of the New York Academy of Medicine He was a member of the New York Surgical and Medical Society, the Celtic Medical Society, the New York County and State Medical Societies, and the American Medical Association

Charles Joseph Dillon, M D , New York City, died on November 4 at St Elizabeth's Hospital after a month's illness, at the age of sixty-nine. Dr Dillon was graduated in 1902 from the College of Physicians and Surgeons, Columbia University, and interned at City Hospital, Welfare Island, where he was on the staff as visiting physician until 1947, when he became consulting physician In 1911 Dr Dillon was appointed a surgeon in the New York City Police Department, was promoted to chief surgeon in 1938, and retired in 1946 He was the author of "The Police Officers and Obstetric Emergencies," an obstetric guide for patrolmen

During World War I, Dr Dillon served as a captain in the Army Medical Corps He had been head of the allergy clinic at New York Post-Graduate Hospital, a resident physician at New York Foundling Hospital, and on the staffs of Misericordia, Roosevelt, Polyclinic, and New Rochelle Hospitals Dr Dillon was a member of the New York County and State Medical Societies and the American Medical Association

Andrew Jackson Fox, M D , of New York City, died at his home in Camden, Maine, on November 3 at the age of ninety-two Dr Jackson was graduated from the Bellevue Hospital Medical College in 1884 and interned at Bellevue Hospital Later he was on the staffs of New York, Roosevelt, and Presbyterian Hospitals in New York City For forty-six years, until his retirement twelve years ago, Dr Fox was chief medical examiner for the Equitable Life Assurance Society of the United States He was a member of the New York County and State Medical Societies and the American Medical Association

George Jesse Ganow, M D , of Port Dickinson, died on October 24 at his home after a short illness, at the age of eighty Dr Ganow, one of Broome County's oldest practitioners, received his medical degree from Hahnemann Medical College in Philadelphia, Pennsylvania, in 1894 Before starting his practice in Port Dickinson, where he had been for thirty-four years, Dr Ganow practiced in Smithville Flats, Sidney, and Oxford, in New York State, and in Oklahoma During World War I he was a captain in the Army Medical Corps

"A safe and effective drug to use in controlling weight gain  during pregnancy."

Coopersmith B.L. Dexedrine and Weight Control in Pregnancy Am J Obst & Gynec (Oct.) 1949

Coopersmith reports the successful use of 'Dexedrine' Sulfate Tablets for weight control in a series of 100 obstetric patients Because 'Dexedrine' curbed appetite and thus enabled these patients to follow their prescribed diets, control or reduction of weight was achieved in virtually all cases  It is noteworthy that other methods, including the use of thyroid, had previously failed to prevent excessive weight gain in these same individuals "Thyroid", Coopersmith states, "increases the appetite and is toxic in many cases"  "Dexedrine Sulfate", the report concludes, "is a safe and effective drug to use in controlling weight gain during pregnancy"

Smith, Kline & French Laboratories, Philadelphia

Dexedrine* Sulfate tablets • elixir

for control of appetite  in weight reduction

[Continued from page 2848]

Dr Ganow was health officer for the towns of Binghamton and Dickinson and the village of Port Dickinson Several years ago he was honored by the Medical Society of the State of New York in recognition of his completion of fifty years in the practice of medicine Dr Ganow was a member of the American Institute of Homeopathy

William McDowell Halsey, M D , of Oswego, died suddenly on October 28 at the age of seventy Dr Halsey was graduated from the Syracuse University College of Medicine in 1902 and had practiced in Norfolk, Virginia, and Ellisburg, New York, before opening his practice in Oswego in 1911 He was assistant surgeon on the staff of the Oswego Hospital and was a member of the Oswego Academy of Medicine, the Oswego County and New York State Medical Societies, and the American Medical Association.

Rosslyn Philip Harris, M D , of Hudson, died on October 27 at the Columbia Memorial Hospital in Hudson at the age of sixty-five. Dr Harris was graduated from the Albany Medical College in 1908 and had practiced in Hudson since 1913 He was chief of the surgical staff at Hudson City Hospital and consultant radiologist at the Columbia County Tuberculosis Sanatorium Dr Harris had served as president of the Columbia County Board of Health, of the Columbia County Medical Society, and of the Tuberculosis Eradication Association of Columbia County During World War II he was chairman of the county's selective service committee supplying doctors to the armed services Dr Harris was a member of the Columbia County and New York State Medical Societies and the American Medical Association

George J Lawrence, M.D , of Flushing, died November 9 at his home at the age of sixty-eight. Dr Lawrence, a major general of the New York National Guard, was graduated from the University of Pennsylvania College of Medicine in 1907 and opened his practice in Flushing In 1916 General Lawrence enlisted as an Army surgeon, serving on the Mexican border, and the next year went to France with the 69th Regiment as a major He was in charge of a front-line field hospital.

At the end of World War I, General Lawrence was with the Army of Occupation in Germany until 1920 Wounded twice during the war, he was decorated with the Silver Star for gallantry in action General Lawrence, who had been a member of the Officers Reserve Corps since 1909 and a member of the New York National Guard since 1908, was promoted to the rank of colonel in 1940 and placed in charge of the organization and command of the 69th New York Guard Regiment. In 1932 he was elected commander of the New York State Department of the American Legion.

Dr Lawrence was consulting gynecologist and obstetrician at the Flushing Hospital and a member of the Queens County and New York State Medical Societies and the American Medical Association.

Franklin Dana Lawson, M.D , New York City, died on October 26 after a long illness, at the age of eighty-three. Dr Lawson was graduated from the College of Physicians and Surgeons, Columbia University, in 1890 and practiced in New York City for several years He served on the staffs of New York and Polyclinic Hospitals Dr Lawson, who was also a voice teacher and former soloist at St. Bartholomew's and St. John's Protestant Episcopal Churches in New York City, studied singing in Paris He was the author of a manual of voice training, "The Human Voice," published in 1944. Dr Lawson founded the Society for the Prevention of Accidents in 1922 and was a member of the Singing Teachers Association of New York City

Arthur Clark Loper, M.D , of Greenport, died October 22 at his home at the age of eighty-one. Dr Loper received his medical degree from the College of Physicians and Surgeons, Baltimore, in 1896, and had practiced medicine in Greenport for fifty-two years He was attending physician at the Eastern Long Island Hospital in Greenport and a former member of the Greenport Board of Education Dr Loper was a member of the Suffolk County and New York State Medical Societies and the American Medical Association

Clarence Edmond Mullens, M.D , of Albany, died on November 9 at the Albany Memorial Hospital after a long illness, at the age of sixty Dr Mullens was graduated from the Albany Medical College in 1912, and served during World War I as a captain in the Army Medical Corps, later being with the Army of Occupation Dr Mullens was attending surgeon at Memorial Hospital and a member of the Albany County and New York State Medical Societies and the American Medical Association

Nishan Alexander Pashayan, M D , of Schenectady, died suddenly on October 28 in his office while examining a patient, at the age of seventy-four Born in Armenia, Dr Pashayan fled his native country in 1890 to escape rule by the Turks and came to America. In 1901 he was graduated from the Albany Medical College and was associated with New York State hospitals before opening his practice in Schenectady A diplomate of the American Board of Psychiatry and Neurology, Dr Pashayan was consultant in neuropsychiatry at Ellis Hospital in Schenectady He was past president of the Schenectady County Medical Society and a member of the New York State Medical Society and the American Medical Association

Norton Isaac Pennock, M D , of Poughkeepsie, died on November 3 at his home at the age of sixty-seven Dr Pennock received his medical degree from Queens University in Toronto, Canada, in 1904 He joined the New York State Department of Mental Hygiene in Ogdensburg and in 1905 transferred to the staff of the Hudson River State Hospital at Poughkeepsie, where he was supervising psychiatrist at the time of his death. Dr Pennock was a member of the Dutchess County and New York State Medical Societies and the American Medical Association

BOOKS REVIEWED

Diseases of the Fundus Oculi. With Atlas. By Adalbert Fuchs, M D Translated by Erich Pressburger, M D Edited by Abraham Schlossman, M D Quarto of 337 pages and 44 colored plates Philadelphia, Blakiston Co , 1949 Three-quarters leather, $30

This is a decidedly valuable translation of a well-known foreign text. It associates the microscopic picture with the eyeground picture seldom found elsewhere in the literature

There is little reference to the contribution of English-speaking countries The American reader will find this detrimental, as much of the recent progress in medical aspects of eyeground diseases has been made in the United States and in England

JOHN N EVANS

Diabetic Menus, Meals and Recipes By Betty M West Octavo of 254 pages New York, Doubleday & Co , 1949 Cloth, $2 95

If every diabetic patient were on the diet, Ch 150, P 80, F 80, this little volume by Betty M West would by all odds be the very best publication of its kind on the market. Unfortunately, as all physicians realize, the diet in every case must be fitted to the needs of the individual, or tailored as it were Diabetic diets vary widely from Ch 150 Gm or less to 250 Gm. or more, protein 80 Gm. or less to 150 Gm or more, fat from 45 to 150 Gm There is no such Utopian entity as a single diabetic diet which will fit all

[Continued on page 2854]

It is deplorable that with very little more effort on the part of the author it would have been possible to make the subject matter of this book less complicated and sufficiently flexible to meet any and every possible dietary prescription of the physician, at the same time retaining as a working foundation the original figures, menus, and recipes as noted

It is unreasonable to expect even the most conscientious patient to struggle through elaborate arithmetical gymnastics in order to arrive at his dietary menu for the day (See page 19) The modern physician seeks to bridge this gap rather than foster in his patient the bases for compulsion neuroses

The reviewer, recognizing the unusual array of appetizing and attractive recipes which might well transform the drab austere diet of the diabetic into the board of a gourmet, will give his patients the advantage of this book sans slide-rules and the musty calculations of a previous generation. He will supply his patients with lists of simple uniform fixed increments of carbohydrate and fat with the suggestion, "Add to Betty West's diet so and so many units of carbohydrate and fat" (No mathematics involved.) Without some such simple adjustment, the unwary diabetic using this book (who will under no conditions be annoyed by a multitude of arithmetical calculations) might to his own great detriment persuade himself that all diabetics should be on the same dietary figures as Betty West It is the bane of the physician when, regardless of counsel and actual needs, his diabetic patient borrows the diet of a neighbor

Much effort has been put into this work of Betty West. A broader viewpoint on the part of the author might well have transformed it from its present status as a diabetic hazard to possibly the most serviceable and practical dietary handbook for the patient in the English language

GEORGE E ANDERSON

Symptoms in Diagnosis By Jonathan Campbell Meakins, M D Second edition Octavo of 542 pages, illustrated. Baltimore, Williams & Wilkins Co, 1948 Cloth, $7 50

The second edition of Meakins' *Symptoms in Diagnosis continues the best features of the first.* It will be a useful introduction to differential diagnosis for the student or young practitioner but contains little which cannot be found in standard textbooks If this volume were half the size and half the price, it would reach a wider audience with little sacrifice of pertinent material. MILTON PLOTZ

More Than Armies The Story of Edward H. Carey, M.D By Booth Mooney Octavo of 270 pages, illustrated. Dallas, Mathis, Van Nort & Co, 1948 Cloth, $5 00

This is a book about an unusually gifted man, a former A.M A. president, whose inner drive, kaleidoscopic yet organized, fulfilled itself in many fields of endeavor Educator, scientist, medical statesman, and outstanding citizen of Dallas, Dr Carey early espoused prepaid health insurance Later, his forthright courage when testifying before a Congressional committee delivered a telling blow, for the time being at least, against what he considered an effort of collectivists to socialize medicine as the first move in the socialization of the American way of life. *More Than Armies* is an inspiring word picture epitomizing the success possible in an atmosphere of enlightened, democratic free enterprise.

MORRIS WEINTROB

Psychodynamics and the Allergic Patient By Harold A. Abramson, M D With Panel Discussion. Duodecimo of 81 pages, illustrated St Paul & Minneapolis, Bruce Publishing Co, 1948 Cloth, $2 50 (An official publication of the American College of Allergists)

The author traces the psychosomatic aspects of hay fever and asthma from Hippocrates to the present time He discusses thirteen complete case records of patients with allergic manifestations and points out the importance of evaluating underlying psychic disorders which might contribute to the symptomatology

The book contains several references and a panel discussion of this subject as arranged by the American College of Allergists at its third annual meeting held in Atlantic City in 1948

MATTHEW BRUNNER

Cornell Conferences on Therapy Harry Gold, M D, Managing Editor Vol. 3 Duodecimo of 337 pages, illustrated. New York, Macmillan Company, 1948 Cloth, $3 50

The third volume of the *Cornell Conferences on Therapy* continues to be informal and instructive There are fifteen discussions of topics ranging from the "Dose of a Drug" to "Treatment of Genitourinary Tract Infections" There is much material unobtainable elsewhere, entertainingly presented, with emphasis on practical clinical problems The very reasonable price of these volumes puts them within everyone's reach MILTON PLOTZ

Blood Transfusion By Elmer L DeGowin, M D, Robert C Hartin, M D, and John B Alsever, M D Octavo of 587 pages, illustrated Philadelphia, W B Saunders Co, 1949 Cloth, $9 00

Progress has been so rapid in the field of blood transfusion that an up-to-date book on the subject is welcome at any time The present volume will no doubt be very well received because it is a practical manual with emphasis on technics and represents the conclusions of the authors based on their own personal experiences Each of the authors is an authority in one or more branches of the fields of blood grouping and transfusion By adopting the plan of dividing the subject matter into chapters, each chapter being written by the author with the most experience in that particular branch, they have succeeded in producing an authoritative work without any weak spots

The theoretic section of the book is only 114 pages in length and makes no attempt to review completely the vast literature on the subject Still, it is comprehensive and clear and deals not only with the A-B groups and M-N types but also in considerable detail with the Rh-Hr blood types The major section of the book deals with technics of blood grouping and blood banking and incorporates more than 450 pages The technical section of the book is logically arranged and clearly presented, making the book invaluable to all those who work in blood banks The book is also ideal for teaching purposes

[Continued from page 2856]

New York, Commonwealth Fund, 1949. Cloth, $3.50.

This book represents a report of a survey conducted by the American Academy of Pediatrics of the facilities available for child care throughout the country.

It was shown that children nearer the large cities receive much more care than those in the rural communities. The latter part of the report has to do with the pediatric education of the physician and stresses the need for more thorough undergraduate and postgraduate education.

The survey merits close attention by the profession. STANLEY S. LAMM

Evaluation of Chemotherapeutic Agents. Symposium Held at the New York Academy of Medicine. March 25 and 26, 1948. Edited by Colin M. MacLeod, M.D. Octavo of 205 pages, illustrated. New York, Columbia University Press, 1949. Cloth, $4.00.

This symposium on the Section on Microbiology of the New York Academy of Medicine is an attempt to evaluate in a general way certain of the many factors involved in the success or failure of treatment.

The individual contributors are leaders in their respective fields. For the most part the subject matter is timely. Rapid progress in antibiotics, however, has outmoded some chapters such as the chemotherapy of rickettsial diseases and viral infections.

The inclusion of cancer chemotherapy adds to the value of the volume, which should appeal alike to clinicians and investigators. LEO LOEWE

Transactions of the Third American Congress on Obstetrics and Gynecology, Municipal Auditorium, St. Louis, Missouri, September 8 to 12, 1947. Sponsored by The American Committee on Maternal Welfare, Inc. Edited by Geo. W. Kosmak, M.D., and Robert N. Rutherford, M.D. Quarto of 412 pages, illustrated. Portland, Ore., The Western Journal of Surgery Publishing Company, 1948. Cloth, $9.00.

The book includes the papers presented at the Third American Congress on Obstetrics and Gynecology in St. Louis during September, 1947. The congress was sponsored by the American Committee on Maternal Welfare and attracted many well-known and authoritative contributors.

The subjects covered in the general and sectional meetings and at the round tables were varied. Cancer of the cervix, pregnancy complications, and cesarean section were covered in greater detail.

The volume presents many of the newer contributions to the literature and should be of great interest to the specialist. ALEXANDER H. ROSENTHAL

The Medical Clinics of North America. Nationwide Number. March, 1949. Octavo. Philadelphia, W. B. Saunders Co., 1949. Published Bimonthly (six numbers a year). Cloth, $16 net; Paper, $12 net.

The current issue of *Medical Clinics of North America* is entirely devoted to an excellent symposium on long-term illness under the able editorship of Eli Rubin. Most of the papers discuss the management of specific varieties of chronic illness. All are good, one or two outstanding. But of greater importance are those devoted to general discussions of our changing attitudes towards disease. Those by Alvarez, Stieglitz, and Ruesch should be read with care, but that by Bluestone, who more than anyone else in this country has been responsible for the increasing attention to this problem, compels our greatest admiration. Much has been written, almost too much, regarding care of the aged, and an attempt is being made to create a new specialty, geriatrics, not a very realistic classification. Bluestone has sensibly pointed out that the important problem is in the providing of care for the chronic ill of any age, and the social implications are clearly pointed out. The editors of *Medical Clinics* are to be commended for their good judgment in providing us with this symposium. MILTON PLOTZ

Hernia. Anatomy, Etiology, Symptoms, Diagnosis, Differential Diagnosis, Prognosis, and Treatment. By Leigh F. Watson, M.D. Third Edition. With illustrations by Helen Lorraine, Willard C. Shepard, and Ralph Sweet. Third edition. Octavo of 732 pages, illustrated. St. Louis, C. V. Mosby Co., 1948. Cloth, $13.50.

This edition, as previous ones, contains a very interesting historical summary. The format makes for easy reading and rapid reference on all related subjects. The drawings and diagrams are well done. Several new chapters have been added; the one on complications, especially that of recurrent hernia, is particularly good. The discussion on early ambulation and vascular complications is lucid and well written. The chapter on the injection treatment of hernia is so well written as to make the procedure look simple and is therefore somewhat dangerous for general use. PHILLIP E. LEAR

Critical Studies in Neurology. By F. M. R. Walshe, M.D. Octavo of 256 pages, illustrated. Baltimore, Williams & Wilkins Co., 1948. Cloth, $4.50.

Although the contents of this book have been previously published elsewhere, they are of such telling importance in understanding the pillars of neuroanatomy and neurophysiology that the earnest student of medicine, as well as the specialist in neuropsychiatry, will be very grateful to the author for critically hand picking these most important contributions. Dr. Walshe's eminence in his field makes doubly significant his foreword, "The Function of Criticism in Medicine," and his perspicacity in integrating his special field with medicine. Research and clinical fundamentals are presented in an enviably lucid literary style concerning the anatomy and physiology of cutaneous sensibility, the motor cortex, pyramidal tract studies including "discrete movement," and the role of pyramidal tract in willed movements. FREDERICK L. PATRY

An Introduction to Medical Mycology. By George M. Lewis, M.D., and Mary E. Hopper, M.S. Third edition. Quarto of 366 pages, illustrated. Chicago, Year Book Publishers, 1948. Cloth, $8.50.

This book justifies its title, and the material is stated clearly and simply. The subject matter is divided into two parts, one of which deals with the clinical, theoretic, and experimental aspects of mycology and occupies about two thirds of the book, while the other is devoted to the laboratory aspects of fungus diseases. There are 103 excellent black-and-white illustrations and two colored plates.

announcing

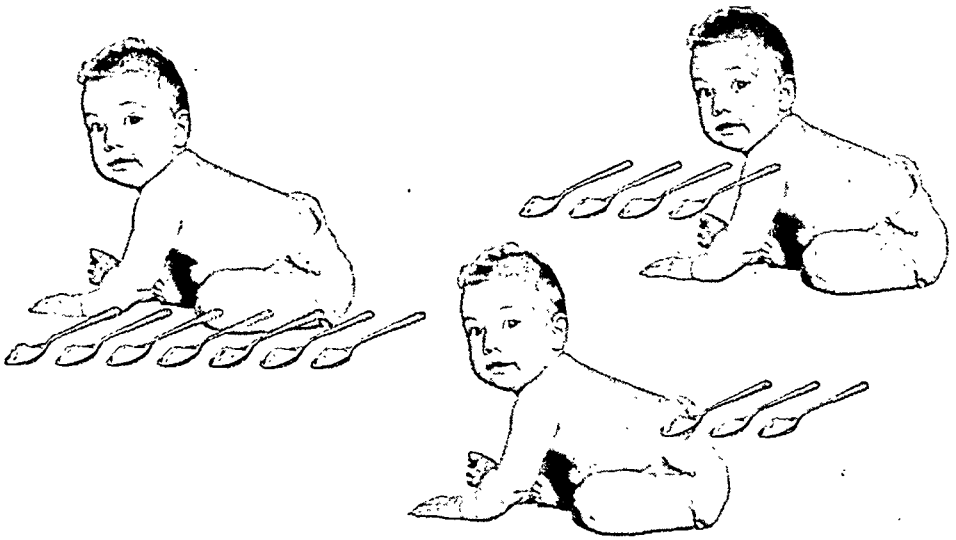
Nuclon

a turning point in the treatment of **the common cold**

Nuclon—a dramatic new application of antihistaminic therapy—
is a truly effective weapon against the common cold.
Nuclon is no ordinary antihistaminic preparation, but a judicious combination of three outstanding ingredients: thenylpyramine fumarate, 'Dexedrine'* Sulfate and acetylsalicylic acid. These three agents work together to perform an essential function in combating the head cold.

Nuclon is so effective that, in the majority of cases, it will either completely abort the common cold or will markedly reduce its duration and severity.

Each adult dose (2 capsules) contains:



Thenylpyramine (methapyrilene) fumarate . .	75.0 mg.
'Dexedrine'* Sulfate	2.5 mg.
Acetylsalicylic acid	5.0 gr.

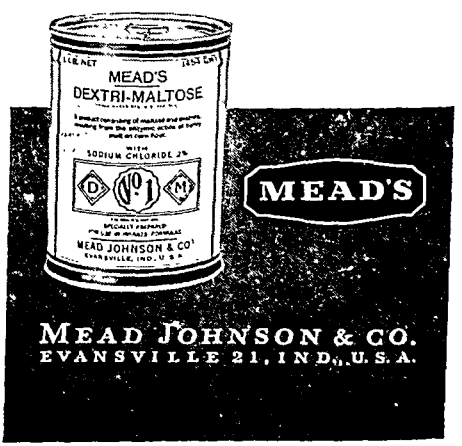
Flexible Formula

FOR AN INDIVIDUALIST



PHYSICIANS concerned with infant feeding have found that the exceptional *flexibility-of-use* offered by Dextri-Maltose* is an important advantage in adapting formulas to the individual requirements of the baby.

By the inclusion of Dextri-Maltose in appropriate amount, the caloric value and carbohydrate content of a formula can easily be adjusted to the infant's special needs.

Since the physician has 5 forms of Dextri-Maltose available, an individual infant's formula may be changed according to various clinical or physiologic indications without disturbance of his routine.

Being a mixture of carbohydrates, Dextri-Maltose offers special qualities of digestibility and slowness of absorption. Hence it is an ideal carbohydrate for use in diarrhea and other gastrointestinal disturbances.

Dextri-Maltose dissolves rapidly in water or milk. It can be used in *your* preferred method of formula preparation. *T.M. Reg. U.S. Pat. Off.

49:29

- **appetite stimulated...**
- **nutrition improved...**
- **greater resistance to infection exhibited...**

The common complaints of infancy—anorexia, undernourishment, slowness of weight gain, propensity to infection—are less frequently encountered when White's Multi-Beta Liquid is part of the infant's diet routine.

Five drops daily of White's Multi-Beta Liquid raises the average infant intake of all clinically important vitamin B factors to a safe level.

For adults, full supplementation of the essential vitamin B factors is provided with just one teaspoonful of White's Multi-Beta Liquid daily.

An excellent prescription ingredient...

Palatable, non-alcoholic and stable, White's Multi-Beta Liquid is ideally suited to prescription use. Compatible with such ingredients as: (1) Tincture Nux Vomica, in equal parts, (2) Elixir Phenobarbital, 1 to 4 parts, (3) White's Mol-Iron Liquid, 1 to 8 parts.

White's *Multi-Beta Liquid*

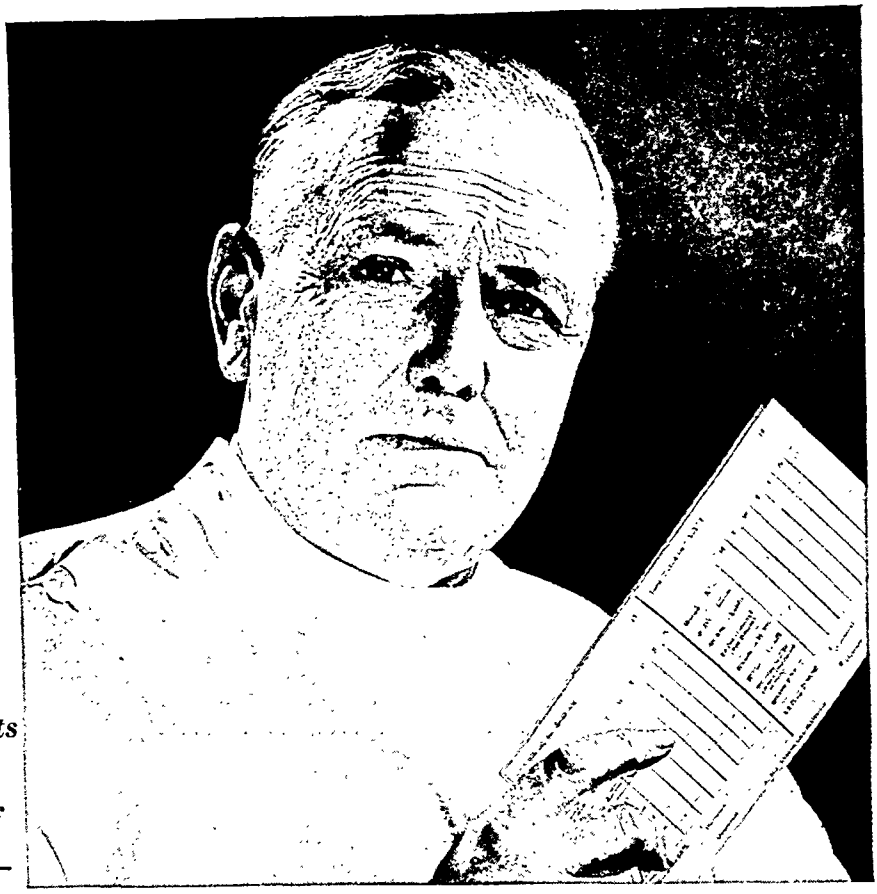
WHITE LABORATORIES, INC., Pharmaceutical Manufacturers, Newark 7, N. J.

Gives the cough relief your patient wants...

Leaves the cough reflex he needs

In the average case, it's usually possible to control the patient's cough—but often it's a real problem to do it without impairing the cough reflex he needs to keep bronchioles and throat passages clear. That's where you'll find pleasant-tasting Mercodol unique!

For Mercodol contains the cough-controlling narcotic[1] that gives better antitussive action than codeine or heroin, yet keeps beneficial cough reflex . . . a superior bronchodilator[2] to relax plugged bronchioles . . . an effective expectorant[3] to liquefy secretions. And you'll find Mercodol notably free from nausea, constipation, retention of sputum, and cardiovascular and nervous stimulation.



MERCODOL®

AN EXEMPT NARCOTIC

The antitussive syrup that controls cough—keeps the cough reflex

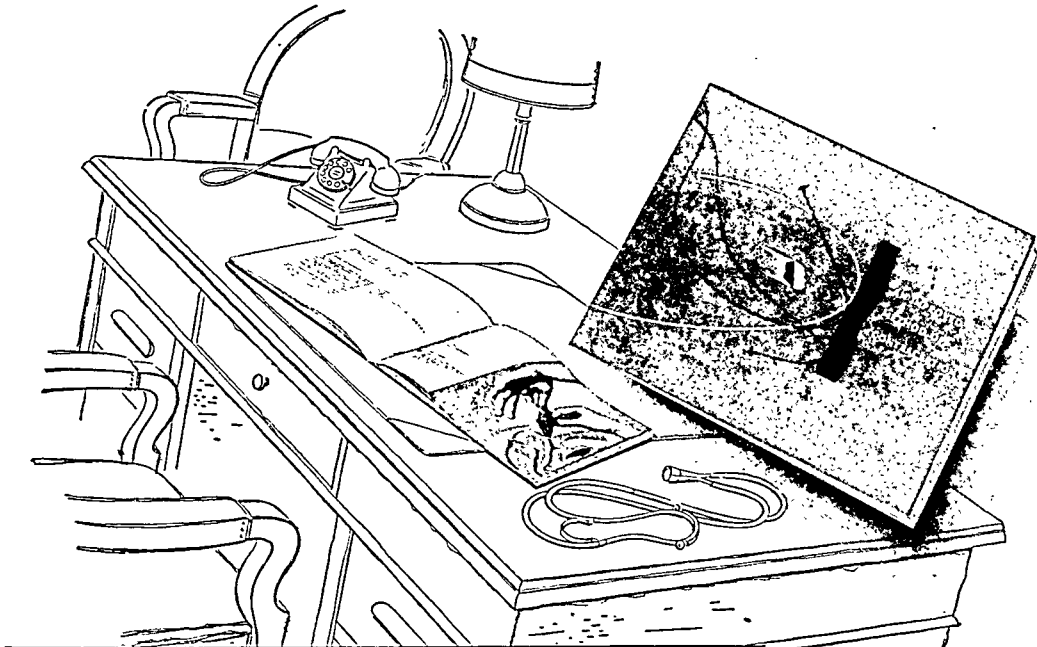
hroat Specialists report on 30-Day Test of Camel smokers—

Not one single case of throat irritation due to smoking Camels!"

● Yes, these were the findings in a total of 2,470 weekly examinations of hundreds of men and women from coast to coast who smoked only Camels for 30 consecutive days! And the smokers in this test averaged one to two packages of Camels a day!



R.J. Reynolds Tobacco Co., Winston-Salem, N.C.

According to a Nationwide survey:

More Doctors Smoke Camels

than any other cigarette!

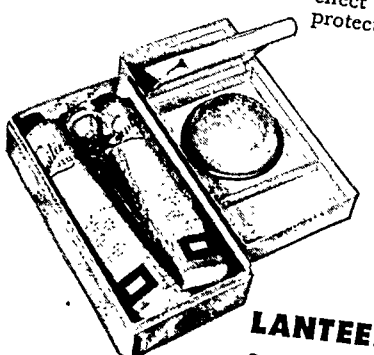
Doctors smoke for pleasure, too! When three leading independent research organizations asked 113,597 doctors what cigarette they smoked, the brand named most was Camel!

AN APPROVED TECHNIQUE

JUST OFF THE PRESS - -

IMPROVED METHOD OF CONTRACEPTION—a twelve-page brochure with five full-color anatomical illustrations—presents a complete description of the improved diaphragm and jelly method of contraception, which, according to the A.M.A. Council on Pharmacy and Chemistry, offers a maximal degree of protection.

The brochure features an improvement in contraceptive technique designed to give greater protection by assuring an adequate supply of spermatocidal jelly around the cervix, where it is needed most.



Available Without Cost to the Medical Profession

On request, Lanteen Medical Laboratories will send without charge:

1. The brochure, "Improved Method of Contraception."
2. The full-size professional package of Lanteen Jelly.

The unusually fine quality and construction of the Lanteen Diaphragm and the rapidly spermatocidal action and soothing effect of Lanteen Jelly are the basis for the safe and effective protection afforded by the IMPROVED METHOD OF CONTRACEPTION.

Lanteen Jelly contains: Ricinoleic Acid, 0.50%; Hexylresorcinol, 0.10%; Chlorothymol, 0.0077%; Sodium Benzoate and Glycerine in a Tragacanth base.

The Lanteen Diaphragm and Lanteen Jelly are accepted by the Council on Physical Medicine and the Council on Pharmacy and Chemistry of the American Medical Association, respectively.

In Chronic Cholecystitis...

First & **Foremost**

chemically pure bile acid derivative made available for therapy, Council-Accepted since 1932, exhaustively studied and most favorably reported by hundreds of investigators, Decholin® remains today a bile acid preparation for use in the medical management of chronic cholecystitis.

The Most Potent Hydrocholeretic,

Decholin multiplies and frees the flow of thinned liver bile. By thus easing biliary evacuation and closely simulating a physiologic drainage of accumulated foreign matter through the hepatic and common ducts, Decholin may lessen the epigastric and right upper quadrant discomfort typical of chronic cholecystitis, improve the patient's tolerance for food and reduce the periods of disability.

Decholin

dehydrocholic acid

3¾ gr. tablets in bottles of 25, 100, 500, and 1000.

Decholin Sodium® (sodium dehydrocholate) in 20% aqueous solution; ampuls of 3 cc., 5 cc. and 10 cc., packages of 3 and 20 ampuls.

The Fifth Edition of "Decholin in Biliary Tract Disturbances" is now available upon request.

During Pregnancy SALT WITHOUT SODIUM

Water retention (excessive gain in weight—pitting edema) is quite common in pregnancy. Sodium, particularly if used excessively, accelerates this process. Vice versa, sodium restriction can prevent water retention.

Neocurtasal, completely sodium free salt, palatably seasons low sodium diets. Neocurtasal looks and is used like ordinary table salt. Available in 2 oz. shakers and 8 oz. bottles.

Constituents: Potassium chloride, ammonium chloride, potassium formate, calcium formate, magnesium citrate and starch. Potassium content 36%; chloride 39.3%; calcium 0.3%; magnesium 0.2%.

Write for pads of diet sheets.

in psychosomatic and menopausal cases

Bellergal® gives excellent results in relieving the functional disturbances of anxiety states, and in gastric and cardiovascular neuroses.

For treatment of that part of the psychosomatic disorder which involves dysfunction of both the autonomic and central nervous systems, BELLERGAL contains the most effective combination of drugs.

ONLY BELLERGAL PROVIDES ALL THREE

1. Sympathetic inhibition with ergotamine tartrate.
2. Parasympathetic inhibition with Bellafoline.
3. Central sedation with phenobarbital.

readily accepted
by your menopausal patients

MENAGEN®

ORAL ESTROGENS, PARKE-DAVIS

oral estrogen therapy that

has no after-taste
imparts no odor

The lingering after-taste, unpleasant breath, and perspiration odor produced by ordinary preparations of natural oral estrogens may prejudice the menopausal patient against therapy. MENAGEN . . . a refined and purified non-conjugated estrogenic preparation intended for oral administration . . . is completely freed of all odoriferous contaminants. Because MENAGEN leaves no after-taste and imparts no breath or perspiration odor the menopausal patient's cooperation in accepting and continuing therapy is more readily secured. The visual attractiveness of the bright flame-colored capsules still further enhances their "patient appeal."

Clinically, MENAGEN Capsules are exceptionally well-tolerated, and (being natural estrogen) impart that feeling of well-being so rarely obtainable with synthetic estrogens. Unvarying potency is assured by rigorous standardization.

MENAGEN: Available in bottles of 100 and 1000 capsules. (Each capsule contains 10,000 International Units of estrogenic activity.)

RELIEF IN 80-90% OF CASES *by the* PERENNIAL METHOD OF SPECIFIC HYPOSENSITIZATION

DIAGNOSTIC AND TREATMENT SETS

State Pollen Diagnostic Sets ($7.50): Dry pollen allergens selected according to state; 1 vial house-dust allergen. Material for 30 tests in each vial.

Stock Treatment Sets ($7.50): Each consisting of a series of dilutions of pollen extracts for hyposensitization, with accompanying dosage schedule. Single pollens or a choice of 21 different mixtures. Five 3-cc. vials in each set—1:10,000, 1:5,000, 1:1,000, 1:500, and 1:100 concentrations.

Special Mixture Treatment Sets ($10.00)
Mixtures of pollen extracts specially prepared according to the patient's individual sensitivities. Ten days' processing time required.

Arlington offers a full line of potent, carefully prepared, and properly preserved allergenic extracts for diagnosis and treatment—pollens, foods, epidermals, fungi, and incidentals.

Literature to physicians on request.

Arlington

THE ARLINGTON CHEMICAL COMPANY
YONKERS 1, NEW YORK

For most effective results in controlling pollinosis, specific hyposensitization should be continued throughout the year. Authorities agree that "desensitization treatment is still the method of choice, and the antihistaminic drugs cannot be considered as substitutes."[1]

for the radiologist

the KELLEY-KOETT

MULTICRON 300MA GENERATOR

with 140 KVP

The Kelley-Koett Multicron 300 MA is a heavy duty X-ray generator with capacity and operating features surpassing any previous diagnostic unit yet available in its range.

The therapy rating is 140 KVP at 10 milliamperes for four hours of continuous operation. Diagnostic rating provides 125 KVP at 300 milliamperes in intermittent operation. Fixed milliamperage control and a unique electronic-mechanical timer make operation outstandingly simple . . . results extremely accurate in every technic.

These and other features of interest to the hospital radiologist are detailed in descriptive literature available on request.

relax the grip of spasm

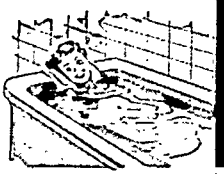
The secret of Donnatal Elixir's unusual spasmolytic efficacy lies in its precise balance of the principal *natural* alkaloids of belladonna, plus its minimal content of phenobarbital • By blocking smooth muscle response to cholinergic nerve impulses, these alkaloids act synergetically to break the links of spastic reaction; and the sedative ingredient helps allay any psychogenic component • Controlled clinical studies—plus broad professional experience—attest its value in gastro-intestinal, biliary, urogenital, respiratory, or central nervous spasm.

for both somatogenic and psychogenic cases

for spasmolysis plus... sedation without toxicity

donnatal elixir

Also available as Donnatal Tablets and Donnatal Capsules



A. H. Robins

Each 5cc of donnatal elixir contains:

Hyoscyamine Sulfate	0.1037 mg.
Atropine Sulfate	0.0194 mg.
Hyoscine Hydrobromide	0.0065 mg.
Phenobarbital (1/4 gr.)	16.2 mg.

When your patient needs

Spa Therapy...

The place is **The Saratoga Spa**

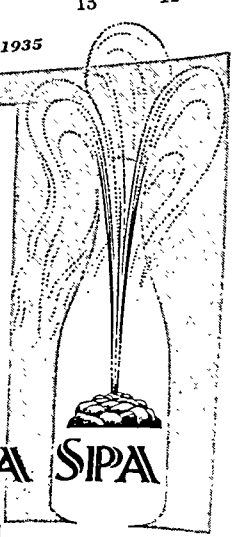
Have you a patient who needs

CORONARY TREATMENT

One hundred seven coronary cases were recently studied. Of this group 33 were females, 74 males, the latter being chiefly from executive and professional walks of life. Not a few were physicians. The average age was 61, the range being 40 to 80 years. The average duration of symptoms was three years, the limits being one month to 10 years. In 32 there was a definite history of coronary occlusion. Twenty-seven had a history of pre-existing high blood pressure, eight of low pressure.

Classified according to the American Heart Association 44 were in Class IIA (activity slightly limited) and 63 in Class IIB (activity greatly limited).

Before beginning a regime each patient was subjected to a thorough physical examination together with all indicated laboratory procedures. The average of the initial blood pressure readings made at this time was 168-95. The final average figure arrived at was 140-81, a difference of 28 mm. of mercury in the systolic and 14 in the diastolic reading. These readings were made after a rest period to obviate the influence of any recent activity.



Symptomatic Change According to Age Groups

Age group	No. Cases	Improvement: Moderate	Marked	None
40-50 . .	11	10	0	1
50-60 . .	41	32	5	4
60-70 . .	34	22	8	4
70-80 . .	18	16	0	2
80- . .	3	3	0	0
	107	83	13	11

The Empire State's Contribution to the Medical Profession

in hypercholesterolemia

safe and effective reduction of elevated blood cholesterol with lipotropic therapy

"Clinical and experimental observations indicate that lipotropic factors [choline, methionine and inositol] . . . prevent or mitigate the deposition of cholesterol in the vascular walls of rabbits and chickens and seem to exert a decholesterolizing effect on atheromatous deposits in man, chickens and rabbits."*

These findings suggest the therapeutic possibilities of lipotropic Methischol in the prevention and possible treatment of atherosclerosis.

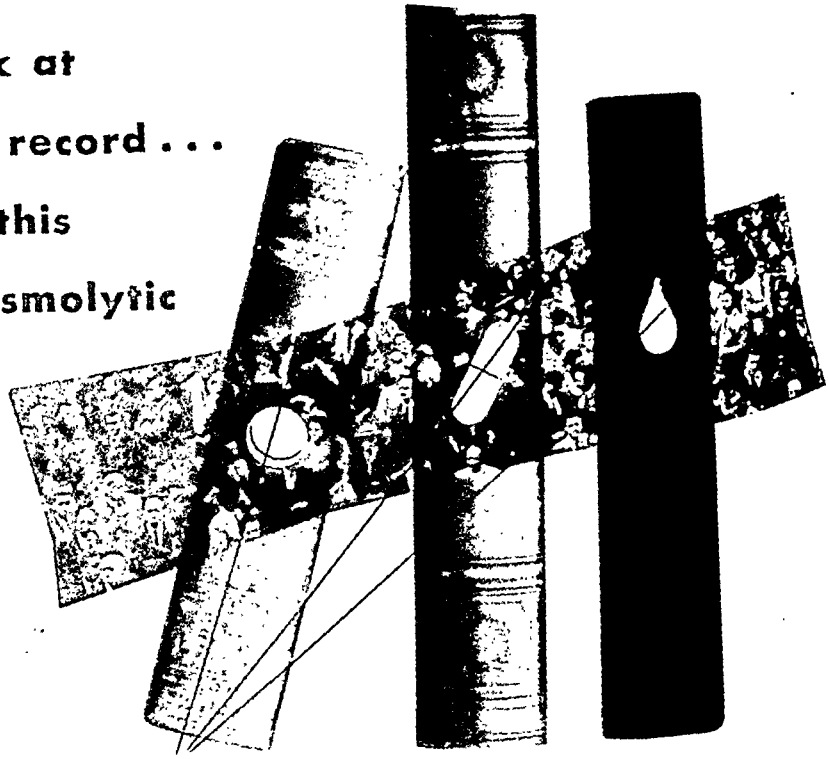
methischol®

Suggested daily therapeutic dose of 3 tablespoonsful or 9 capsules contains:

*Choline Dihydrogen Citrate (Choline . . . 1 Gm.)**	*2.5 Gm.*
dl-Methionine	*1.0 Gm.*
Inositol	*0.75 Gm.*
Liver Fractions from	*36.0 Gm. liver*
**present in syrup as 1.15 Gm. choline chloride*	

Supplied in bottles of 100, 250, 500 and 1000 capsules, and 16 oz. and one gallon syrup.

methischol



combines major lipotropic agents for specific therapy in reparable liver damage . . . cirrhosis, fat infiltration, functional impairment, toxic hepatitis, infectious hepatitis.

maintaining urinary antisepsis without distressing the patient

Comprehensive clinical evidence establishes that MANDELAMINE (methenamine mandelate) is effective against *Escherichia coli, Staphylococcus aureus* and *albus,* and certain streptococci. Comparative studies indicate its bacteriostatic and bacteriocidal effectiveness to be approximately the same as that of the sulfonamides or streptomycin.

Because MANDELAMINE therapy is exceptionally well tolerated, patients willingly adhere to the prescribed regimen.

DOSAGE: Adequate dosage is important; for maximum effect, adults should take 3 or 4 tablets t.i.d.; children in proportion.

Complete literature and samples sent to physicians on request.

6 *outstanding features*

- Has wide antibacterial range
- *No supplementary acidification required (except* when urea-splitting organisms occur)
- Little or no danger of drug-fastness
- Is exceptionally well tolerated
- Requires no dietary or fluid regulation
- Simplicity of regimen—3 or 4 tablets t.i.d.

For mixed infections

Chronic, infected, cutaneous ulcers of hypostatic, decubital or diabetic origin, usually respond rapidly to topical Furacin therapy. Of 81 such cases specifically mentioned in the literature, good results were obtained in 65. The infection, odor and discharge usually diminished promptly without delay of healing. Furacin® brand of nitrofurazone, is available as Furacin Solution (N.N.R.) and Furacin Soluble Dressing (N.N.R.) containing Furacin 0.2%. These preparations are indicated for topical application *in the prophylaxis or treatment of infections of* wounds, second and third degree burns, cutaneous ulcers, pyodermas and skin grafts. *Literature on request.*

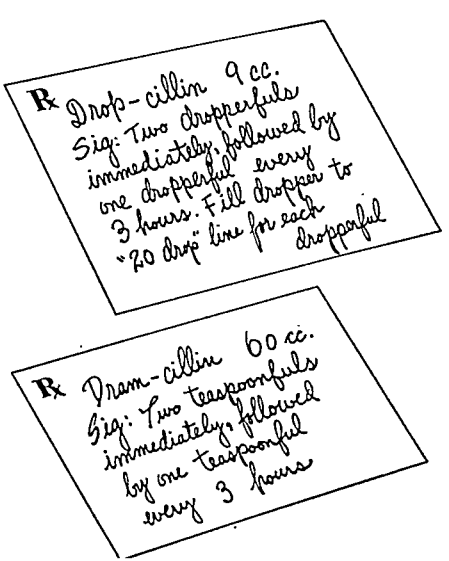
*50,000 units of penicillin**

in this dropper

White's **drop-cillin**



*100,000 units of penicillin**

in this teaspoonful

White's **dram-cilli**

... both with a delicious vanilla flavor

SUPPLIED:

DROP-CILLIN—in 9 cc. "drop-dosage" bottles containing 600,000 units of penicillin. Accompanying calibrated dropper (filled to mark) delivers approximately 20 drops (0.75 cc.) containing 50,000 units of penicillin.*

DRAM-CILLIN—in 60 cc. "teaspoonful-dosage" bottles containing 1,200,000 units of penicillin. Each teaspoonful (approx. 5 cc.) provides 100,000 penicillin.*

*(*buffered penicillin G potassium*)

White's **DROP-CILLIN** has been specially formulated to provide a "drop-dosage" form of penicillin for oral administration to infants and young children. It may be administered directly or added to the first ounce or two of formula without significantly altering the taste or appearance of the formula.

White's **DRAM-CILLIN** is a most potent liquid oral penicillin. Its pleasant taste and deep ruby-red color appeal to both children and adults alike.

In suitable indicated cases, Drop-cillin and Dram-cillin obviate the use of injections with their attendant fear and discomfort, especially for the young patient. In addition, the nurse or mother is relieved of the chore of crushing tablets and forcing medication upon recalcitrant patients. Full and accurate dosage, with willing adherence to the dosage schedule, is assured.

In prescribing, please note:

White's **DROP-CILLIN**—50,000 units in one dropperful
White's **DRAM-CILLIN**—100,000 units in a teaspoonful

Supplied to the pharmacist as a dry stable crystalline powder. Dispensed as freshly prepared solutions, Drop-cillin and Dram-cillin will retain full stated penicillin potency for seven days when refrigerated.

WHITE LABORATORIES, Inc., Pharmaceutical Manufacturers, Newark 7, New Jersey

White's

. . . FOOT ACTION!

THE mechanical foot action of Hanger Artificial Legs allows a close approximation of natural walking for their wearers. The forward and backward motion and rubber cushions absorb shock and give the flexibility of motion so important in maintaining an even stride. This is one more example how the goal of Hanger design and development is to allow the amputee to resume life's normal functions. Throughout, Hanger Limbs are constructed of a few parts simply assembled to reduce unnecessary breakdowns and repairs.

Addison's Disease

Addison's disease, characterized by asthenia, weight loss, pigmentation, hypotension, hypoglycemia and anemia, is the most distinct indication for Adrenal Cortex Extract Armour. Since the disease varies greatly in severity in different patients and in the same patient at different times, the dosage must be adapted to the individual case.

Some patients are controlled by as little as one c.c. daily, whereas others require 10 c.c. or more. When the Addisonian patient is exposed to some unusual stress such as infection, surgery, trauma or excessive physical exertion, massive dosage (50 c.c. or more) may be required. Indeed, there are many published reports which indicate that the adrenal cortex steroids are of great importance in helping normal (non-Addisonian) individuals meet such stress. Adrenal Cortex Extract Armour is also indicated in connection with the surgical removal of adrenal tumors to meet both the stress of the operation and to compensate for deficiency of cortical secretion.

Adrenal Cortex Extract ARMOUR

is a highly concentrated and purified extract of adrenal glands, essentially free of epinephrine and containing a mixture of the cortical steroids as isolated by Kendall and others. It is supplied in 10 c.c. rubber-capped vials, and standardized to contain not less than 50 dog units per c.c.

Have confidence in the preparation you administer—specify "Armour"

When Lipotropic Action

IS THE THERAPEUTIC NEED

INOSITOL

CSC

Inositol, although widely found in nature in both free and combined forms, owes its clinical importance to its lipotropic activity.

The lipotropic action of inositol was first detected in rats,[1, 2] and was later also demonstrated in human subjects.[3] This vitamin B complex member is capable of mobilizing fat in the liver, reducing the severity of fatty infiltration of dietary origin, or preventing it entirely. The lipotropic action of inositol is being investigated extensively in many clinical studies, particularly in patients with arteriosclerosis, peripheral vascular disease, coronary artery disease, and cirrhosis with and without ascites.[4, 5]

Excellent therapeutic results have been obtained by many investigators in the treatment of these diseases, but the limited experience to date makes impossible absolute claims regarding clinical indications.

The dosage of inositol has been tentatively placed at 1.0 Gm. three or more times daily, given after meals. Diets should be high in protein, other B-complex vitamins, and carbohydrate.

Inositol-C. S. C. is available on prescription in 0.5 Gm. capsulettes (capsule-shaped tablets) in bottles of 100.

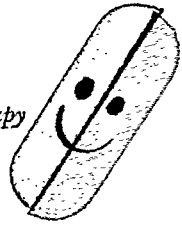
'Beminal'®

For versatile "B" therapy



The 'Beminal' family provides a choice of five distinctive forms and potencies for the effective treatment of vitamin 'B' deficiencies. Each is designed to fill a particular need.

1. 'Beminal' fortified with Iron, Liver and Folic Acid Capsule No. 821 is suggested for the treatment of iron deficiency anemias, certain macrocytic anemias and as adjunctive therapy in pernicious anemia.
2. 'Beminal' with Iron and Liver Capsule No. 816 is recommended for the treatment of the various types of iron deficiency, occurring either as frank hypochromic microcytic anemia or as the less pronounced anemia of nutritional origin.
3. 'Beminal' Forte with Vitamin C Capsule No. 817 is suggested when there is severe depletion of the patient's nutritional stores due to either prolonged dietary inadequacy or nutritive failure as a result of organic disease.
4. 'Beminal' Forte Injectable (Dried) No. 495 provides, when reconstituted, a high concentration of important vitamin B factors for intensive therapy.
5. 'Beminal' Tablets No. 815 may be of value if the vitamin B complex deficiency is mild or subclinical.

Why Many Physicians Write It

CARSTAIRS

when whiskey is indicated

MORE and more well-informed physicians are recommending light blended whiskey to their patients when whiskey is medically indicated. Reason:

Neutral spirit blends contain few congeners, such as fusel oil, tannins, aldehydes, esters, furfurals, acids, etc. That means they're not only light but mild, too. What's more, they're usually around only 86 proof (43% alcohol by volume).

One of America's leading whiskies of this type is Carstairs White Seal. It is blended with care ... by expert distillers devoted to the highest quality standards. Their insistence on perfection has made Carstairs famous as the Perfectly Balanced Blend.

Whenever whiskey is indicated, may we suggest that you recommend that superb blend—Carstairs White Seal—to the patients in *your* care?

Gratifying Relief

from distressing

URINARY SYMPTOMS

Distressing symptoms of urinary tract infection such as urinary frequency, pain and burning on urination can be relieved promptly in a high percentage of patients through the simple procedure of administering Pyridium orally.

With this easy-to-administer and *safe* urinary analgesic, physicians can often provide their patients with almost immediate relief from distressing urinary symptoms during the time that other therapeutic measures are directed toward alleviating the underlying condition.

Pyridium is virtually nontoxic in therapeutic dosage and can be administered concomitantly with streptomycin, penicillin, sulfonamides, or other specific therapy.

The complete story of Pyridium and its clinical use is available on request.

VOLUME 49 DECEMBER 15, 1949 NUMBER 24

Editorials

Christmas, 1949

To every member of the Medical Society of the State of New York, the officers of the Society, the Publication Committee, the Editors, and the Associate Editorial Board, extend heartiest greetings and best wishes for a joyous Christmas.

All over the world the tenuous flame of the torch of freedom is flickering; here and there its light has ceased to penetrate the surrounding murk; the quenched embers glow secretly, if they yet retain any remaining warmth, only in the recesses of men's souls. There they are kept alive, secure by hope, love, charity, and the help of God.

The evanescent tyranny of manlike beasts, annoying temporary oppression by officials vested with a little brief authority, the evanescent exercise of excessive controls by big governments, bigotry, meddlesomeness, unkindness, stupidity can be endured because of the certainty of their very impermanence and the sure knowledge that the small, continuing spark of spiritual aspiration, fanned by hope, will surely burst again into strong bright flame to light the faltering progress of mankind onward and upward. Merry Christmas and, with Tiny Tim, "God bless us all—every one."

To Thyself Be True

It is related of the late Peter Marshall, D.D., formerly chaplain of the U.S. Senate, that in one of his opening prayers he said: "O God! Give us clear vision that we may know where to stand and what to stand for —because unless we stand for something we shall fall for anything."[1]

The code of ethics of the medical profes-

[1] Daily News, Nov. 15, 1949, p. 4.

sion and the twelve-point program of the American Medical Association, respectively, have fulfilled the requirements of this spicy invocation, the former for centuries and the latter for decades in so far as American medicine is concerned. Support of the Medical Practice Act in this State by the majority of the physicians, the long and important history of which Act we have recently condensed in these columns, is another striking example of a corollary fulfillment of the spirit of the good chaplain's prayer, *in the public interest by the profession.*[2]

We are about to face again in this State the annual onslaught of quackery as we have done in every recent session of the Honorable the Legislature. That onslaught must be met determinedly; we must know where we stand and what we stand for; but, more importantly, the legislators and the public must understand it, too. If they do not, there is no telling what they may fall for! Chiropractic, naturopathy, all the devices shrewdly calculated to serve as short-cuts to the pretension of real medical knowledge and skill may be expected to parade their shallow profundity, their shoddy charlatanism, their evasive humbuggery in crafty legislative proposals for licensure.

Citizen-dupes will be marshalled to support this onslaught; legislators will be swamped with mail; letters, petitions, postcards will carry the message that the public must have its favorite quackery legalized.

Little of the mail will oppose such bill or bills as may be introduced, over the signature of doctors, if past experience is any criterion. In 1949 the chiropractic bill barely failed of passage. This JOURNAL again urges all doctors of medicine in the State to tell their legislators where the individual doctors stand and what they stand for; otherwise.....

[2] NEW YORK STATE J. MED. 49: 2255 (Oct. 1) 1949.

The Medical Problems of Rural Health

These problems could be boiled down to the statement: Not enough of anything available where needed. The Medical Society of the State of New York has for years studied the needs of the rural areas for better medical service, more medical and ancillary personnel, expanded hospital and diagnostic facilities, and possible ways of providing them. The New York State Department of Health has also given these problems a vast amount of study looking to the solution of many public health and sanitation needs. Jointly, the Commissioner of Health and the Council Committee on Public Health and Education have for long conferred and have jointly and severally obtained action over the years by which beginnings have been made in solving some of the problems. Much remains to be done. Vast amounts of information as to needs are available as the result of former and continuing study. What about more action?

In the November issue of *Health News*, Dr. Herman E. Hilleboe, Commissioner of Health, makes some very concrete suggestions. He urges a review of the steps taken by the Michigan State Medical Society:

> Following this [A.M.A.] conference the State of Michigan began immediately to a The Michigan State Medical Society put asi $2,000 for a State conference. Early in 194 a State meeting on this subject was held an 28 lay organizations were enlisted as cospor sors. As a result of this meeting, five practic steps were taken. (1) The Michigan Founda tion for Medical and Health Education wa formed to advance loans to medical student who agreed to enter rural practice. (2) A physician placement service was organized under the auspices of the State Society. (3) A nurse recruitment program was organized. (4) A plan for more local community health councils was formed. (5) A yearly State conference on rural health was determined upon.
>
> The Michigan Foundation for Medical and Health Education began its operation by soliciting funds from lay organizations, wealthy citizens, and other possible sources. By January, 1949, it had $100,000, and it will award sometime this month its first scholarship loans to medical students who are willing to go into rural practice.

Studies have been under way by the Society for some years relating to the problems of rural medical service peculiar to this State and with the object of eliciting the help and interest of the Grange, the 4-H Clubs, and the Joint Hospital Survey and Planning Commission. Basically, the task of increasing the number and improving the training of general practitioners has been recognized as of first importance. Already in several sections of the State experimental work is going forward in an effort by medical schools and hospitals to increase hospital internship training in general practice and to revive something like the old preceptorships, the students actually working in the offices of and making calls with rural medical practitioners. The House of Delegates at the 1949 Annual Meeting suggested to the Council the possible formation of a Section on General Practice. The Council is recommending the formation of such a section now. Also in October of this year the New York State component of the Academy of General Practice held its first scientific meeting at Syracuse.

A survey of the needs for medical personnel has been completed recently by the State Medical Society; the Joint Hospital Survey and Planning Commission is now gathering factual material relative to existing and needed facilities; studies are in progress by the Medical Society of the State of New York on the feasibility of the establishment of group practice in rural areas, and the Women's Auxiliaries of the State and county societies have been active in assisting nurse recruitment and in the study of rural health problems. The further steps suggested by the Commissioner of Health will unquestionably be considered by the Council Committee on Public Health and Education at an early date, including the Kansas experiments along this line.

The Hospital and the Physician

The care of the sick in the average American home is rapidly disappearing. This applies not only to serious illnesses, but also to a multiplicity of minor ones as well. For many and adequate reasons, the hospital has been substituted for the home. Better medicine can be practiced there, not only from the standpoint of the physician, but, more important still, because of the better results to the patients. It is apparent, therefore, that, in the future, hospital care will continue to increase in quantity, prestige, and value. There is no possibility that it will decrease.

Over the years, moreover, the hospitals, especially the larger ones, have continually multiplied their functions. In addition to the scientific care of the sick they have become institutions of social service, of education for doctors, nurses, social service personnel, and others, ranging from librarians to potential hospital superintendents. Some, as those connected with teaching centers, are engaged in the tremendously expensive problems of the education of medical students, as well as medical research.

The larger part of the hospital load is carried by the voluntary hospitals. Their income is derived largely from patients. It may be supplemented by community chest contributions, or from philanthropic gifts, now rapidly diminishing. They have been harassed by ever-increasing costs for labor, food, and materials. They are, in fact, threatened with insolvency. State as well as national government is keenly aware of its degree of insolvency and anticipates subsidies.

Subsidies are not an evil in themselves. They can be constructive, but also they may be destructive. They can be constructive if they relieve the hospital of the financial burden of the education of so many people who not only make the hospital more efficient but also will serve the community in the future. These are now largely paid for at the cashier's office by the patient.

Subsidies can be constructive, if they pay for intelligent research. A constructive idea also would be one for the establishment of a commission to study the problems of hospitals, both structurally and functionally, in relation to the community in which they might serve. Such a commission should be guided by the invariable rule, old-fashioned though it may be, that no hospital should be

built beyond the capacity of the local community to finance it. One hundred fifty thousand dollars of extra cost due to unnecessary cubic feet in rooms or halls, or to ornate decorations, usually makes the difference between solvency and insolvency when it comes to amortizing the mortgage.

Far too many hospitals are doomed to financial failure as soon as they are completed. This is largely due to the fact that the construction is not rigidly controlled by honest bookkeeping as applied to anticipated income and expense. This should be done while the hospital is still on paper—before a stone is laid. Instead of this, the guiding light is the ideas of visionary and expansive planners. Good medicine and surgery are performed by men—not by marble columns or wide corridors.

Under the political philosophy of recent years it is assumed that man is unable to care for himself and his future, that he needs constant help and, what is more important, supervision. The power of unlimited money as subsidies has caused a convergence of welfare workers on every conceivable point of attack. One of these is the hospital which, in turn, can be used for the expansion of the same ideas.

Destructive subsidies, therefore, are those that build or subsidize hospitals directly, because control must inevitably follow. This endangers the autonomy of the hospital and, secondly, the autonomy of the physician.

In New York State the lay board has legal control of the physical plant, the finances, the medical staff, the nursing staff, and the personnel. The physician is legally appointed to the staff by the lay board, and, although the latter may consult the medical staff as to its appointments, they are under no obligation to follow such a course. In spite of this, however, the relationship between the lay boards and the medical staffs of our hospitals has usually been amicable. Each has kept to its field and worked together for the common good. The lay board has retained its power for local service, and the physician his independence. This will probably remain so as long as the hospital itself can remain solvent. Should it have to accept subsidy, things might be altered.

It is unthinkable that subsidy would long continue from any source without control following from the same source. All previous experience proves that. The nature of that control cannot be foreseen, but undoubtedly it will be flavored by the social theories of those who exercise it. It can be expansive if backed by the general fund of the taxpayers' money.

It behooves the doctor, therefore, while there might be time, to consider actively the solvency of his own castle—of his workshop. He should join actively with the lay board in sympathetic understanding, so that both may become allergic to unnecessary expense and debt—to the end that his hospital remains solvent. He should, by studying the functional activities of the hospital, of himself, and of his colleagues, make medical care in his own institution more efficient and less expensive. He might also be stimulated toward this activity by the thought that, if he does not do it, he might quickly be in jeopardy.

At present he is working in a place controlled by his friends, although he is but one of the personnel. Should his friends be superseded his security and dignity would be imperiled. The intense competition among physicians, so valuable to the patient, would also disappear, and the quality of medical care would suffer in consequence.

The Creeping Paralysis of Dependency, II

Physicians are in a position to assess the subtle corruption of dependency; they have to contend with it in many cases of illness in which it is a factor—the dependency which demands "security" as a sop for the vague fear that all is not well, that creeping paralysis of the will which aggravates sickness, prolongs recovery, provokes relapses, and drives the cost of sickness ever higher, the cost of living ever upward, makes the tax bill ever greater; the dependency which exhausts the coffers of private charity, over-

loads public assistance, permits private taxation to be levied, for example, on every ton of coal mined to be paid by every coal-using citizen for the "health and welfare" of an elite protectorate who *may* work one or two days a week *if permitted.* Surely, they must need a "health and welfare" fund of huge proportions since their house is "empty, swept, and garnished,"[1] ready for occupancy by the seven devils: idleness, vainglory, pride, preferment, tyranny, hate, and fear.

Within the labor movement, dependency grows constantly, witheringly as a result of the pursuit of the will o'-the-wisp "security." In the larger field of national affairs, authority is proposing "social security" on an ever more grandiose scale, apparently unmindful that "security," whether social or not, is preceded by debt, accompanied by dependency, and followed by destruction.

Consider the current public debt, consider the current commitments of this nation to others, consider the proposed domestic legislation to increase "security" and increase dependency, citizen-taxpayers! Shall we travel that road to its end? Who then can be secure, from what and for how long?

[1] Matthew 12 : 44.

Current Editorial Comment

A Great Medical Discovery. Some highly placed but invisible figure in the administration of the United States government has made during the past sixteen years an important medical discovery. It is that of visual fatigue.

The average reader of the average paper in this country is easily bored with counting ciphers. Members of the generation awed by the accumulation in private hands of the Ford, Rockefeller, and Carnegie millions now see the next generation led down the garden path in precisely the opposite direction, but on a vastly more magnificent scale. The amassing of millions in private hands is a matter for public execration. The spending of billions by government is one for public admiration. We quote from the financial section of the New York *Times*, Sunday, October 9, 1949:

> VAST EXPENSE SEEN IN SOCIAL SECURITY
>
> Possible annual cost is placed at $13,000,000,000 fifty years in the future
>
> In 10 years the annual cost will be $3,800,000,000

And on top of this we, the nation with the best record of national health, are being asked to institute a system of socialized medicine.

We gladly invite the accusation of naiveté by asking this question: Why is it moral for governments to do things for which a private individual would be put in jail? Upon what meat do these our politicians feed, that they are grown so omniscient? The first question a private banker would ask of a client wishing to launch a new idea—a new vision—if you please, is "What is your credit rating?"

We do not wish to put too much of a strain upon our readers, but we ask them to consider for a moment Government as an individual—Mr. Smith. Mr. Smith's heart bleeds for the unfortunates who cannot themselves meet the cost of medical care. For their benefit he would tax the entire people, sick and well alike. By this means he would benefit a proportion of the nation. The majority of taxpayers—and those having money to pay taxes are usually the smarter or the more industrious, plodding, conscientious proportion of the population—would not take long to discover that, if they had to shell out money for the care of the sick no matter how well they were themselves, they would lose their incentive to keep well. Heart Associations, Cancer Clinics, Foundations for Infantile Paralysis, and Tuberculosis and Health Associations keep the public continuously aware of the pitiful—and frequently deserving—plight of sufferers from such plagues.

The public is not aware, but the medical profession is, of the vastly greater numbers of people with psychosomatic ailments who are not ill because they sometimes cannot afford to be. Neither is Mr. Smith. So what is Mr. Smith's next move in his program of measureless devotion to the public welfare?

He sues the Atlantic and Pacific Com-

pany because, through their far-flung combinations, their efficiency methods, and their business acumen, over many years they have succeeded in supplying the underprivileged masses with cheaper food. They are Big Business, which for some reason he doesn't like. He doesn't see the good results because he resents the methods by which they are attained.

If Mr. Smith were submitted to an examination by a board of impartial psychiatrists, we think he might be adjudged a schizophrenic.

We find this transposition of government to individual very disturbing. What do you think?

Retail Druggists' National Association. In September, the Federal Security Administrator's speech to the National Retail Druggists' Association sought to win the support of this organization for the administration's national compulsory health insurance program.[1]

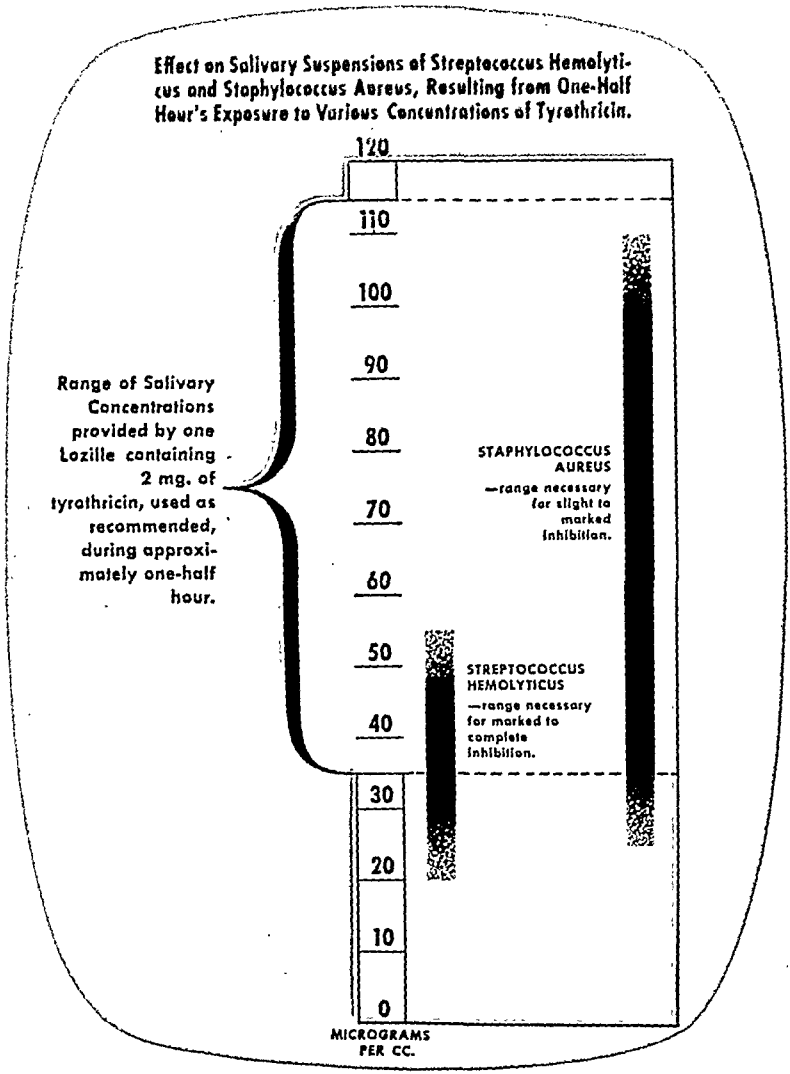
Refusal of the National Association of Retail Druggists to accept the Federal Security Administrator's proposal for a compulsory health insurance program has been hailed by Mr. Robert L. Lund, president of the St. Louis College of Pharmacy, as the rejection of "an appeal to the pocketbook rather than to principle."

Mr. Lund referred to the action of NARD's 51st annual convention in September, which reaffirmed opposition to socialized medicine despite a personal appeal by Mr. Oscar R. Ewing, FSA chieftain. A resolution objecting to the political health scheme was passed by delegates after Ewing's speech in which he openly stated that "I do not see how the retail druggist can fail to profit enormously" under the project.

Pointing to the "specious and offensive logic" of the speech, Mr. Lund said that Ewing "misunderstood the character of the druggists of America in his effort to bring national health to the level of merely their stock in trade, cash registers, and profit."

"It's reassuring to all of us who are concerned for free American institutions to know that the druggists of this country believe that the question of the people's health should be decided on principle and on the basis of achievements of our existing medical system, recognized to be the finest in the world," Lund continued.

"The druggists of America have shown clearly that, so far as they are concerned, this question is not to be answered by any appeal to short-term, selfish, commercial interest, but by reference to the true principles and values involved—the welfare and the freedom of all Americans."



This attitude of the retail druggists as expressed by the president of the St. Louis College of Pharmacy seems to us to be a fitting rebuke to salesmen of national compulsory health insurance who can apparently find so little to commend it that they must resort to an appeal to the most offensive and sordid commercialism.

OFFICE MANAGEMENT OF VENEREAL DISEASES

"The time has now arrived when the diagnosis and treatment of venereal diseases should properly revert to the office of the private physician . . . ." are the words prominently displayed on the cover of a valuable and useful booklet recently issued by the Bureau of Social Hygiene of the New York City Department of Health, in cooperation with the New York State Department of Health and the United States Public Health Service. This booklet outlines for the physician the management of venereal disease patients and is up-to-date on the new methods of treatment, including penicillin and other antibiotic agents, although the final word on these remedies cannot be written at this time.

The publication is well worthy of the attention of the practitioner and may be obtained from the Department of Health, 125 Worth Street, New York 13, New York.

Effective Salivary Levels of Tyrothricin

Used as recommended, one Lozille maintains for approximately *one-half hour* salivary tyrothricin levels as shown in chart.

The sustained salivary concentrations insure broad antibacterial action against gram-positive organisms responsible for acute oropharyngeal infections.

Tyrothricin, unlike topical penicillin, is remarkable for its *lack of local toxicity*. Pleasant-tasting, Lozilles also provide propesin, for non-toxic, long-lasting analgesia.

Each Lozille contains *2 mg.* of tyrothricin and 2 mg. of propesin. Supplied in vials of 15 Lozilles.

GASTRIC RESECTION FOR PEPTIC ULCER IN POOR-RISK PATIENTS

JOHN D. STEWART, M.D., HARRY W. HALE, JR., M.D., and JAMES E. HIX, M.D., Buffalo, New York

(*From the Edward J. Meyer Memorial Hospital and the Department of Surgery of the University of Buffalo School of Medicine*)

IN CONSIDERING the advisability of any surgical operation, the benefit likely to be obtained by the patient must be balanced against the risk of the procedure. Furthermore, the patient is interested in the risk of operation in his own case with the particular circumstances at hand, rather than in statistical abstractions. The surgeon must estimate the patient's physiologic reserve and the effect of the surgical lesion as well as incidental disease, as these may bear on his fitness for surgical operation. At the same time the surgeon must know what the risk of the proposed operation amounts to in his own hands with the facilities available to him.

Although the term "elective" is used for surgical operation under certain conditions, actually the indications for surgical treatment are always relative, not absolute. Consequently, with advances in the art and science of surgery, its proper scope broadens. The surgeon, as well as the referring physician, must always keep this point in mind in order to advise the patient wisely. For the physician to gauge the place of a surgical operation on the basis of its benefits and dangers twenty years ago or even ten years ago is manifestly unreasonable and unfair to the patient. The present study was undertaken to obtain information on the current risk of the operation of subtotal gastric resection, as performed for the relief of complications of peptic ulcer in a depleted, poor-risk group of patients. The series comprises 120 consecutive cases recently operated on by the senior author.

The Hoffmeister type of subtotal gastrectomy has been used almost exclusively, and the anastomosis has been of the antecolic, short jejunal loop variety. Actual measurements have shown an average excision of 80 per cent of the stomach. When the ulcer was duodenal, it was usually, but not always, excised. In the penetrating duodenal ulcer with extensive involvement of surrounding tissues and a pancreatic crater, the operation described by Allen has at times been employed with satisfaction.[1] Ether anesthesia by closed system and endotracheal catheter has been used, and early ambulation has been routinely practiced with the patients walking within twenty-four hours after operation. Penicillin has been used postoperatively and in a few cases streptomycin as well. Blood transfusion has been freely used during and after operation, not only in the acutely bled-out patients but in the nonhemorrhagic cases.

The indications for gastric resection in the 120 cases are shown in Table 1. The commonest finding was intractability to medical management, which usually meant penetration of the ulcer to such an extent as to involve neighboring structures outside the stomach or duodenum. In many instances, the ulcer had actually burrowed into other viscera. Often there were several of the so-called surgical complications of peptic ulcer present in the same patient. Thirty-four of the patients were suffering from acute massive hemorrhage and were operated upon within twenty-four hours after admission to the hospital.

GASTRIC RESECTION FOR PEPTIC ULCER IN POOR-RISK PATIENTS

JOHN D. STEWART, M.D., HARRY W. HALE, JR., M.D., and JAMES E. HIX, M.D., Buffalo, New York

(From the Edward J. Meyer Memorial Hospital and the Department of Surgery of the University of Buffalo School of Medicine)

IN CONSIDERING the advisability of any surgical operation, the benefit likely to be obtained by the patient must be balanced against the risk of the procedure. Furthermore, the patient is interested in the risk of operation in his own case with the particular circumstances at hand, rather than in statistical abstractions. The surgeon must estimate the patient's physiologic reserve and the effect of the surgical lesion as well as incidental disease, as these may bear on his fitness for surgical operation. At the same time the surgeon must know what the risk of the proposed operation amounts to in his own hands with the facilities available to him.

Although the term "elective" is used for surgical operation under certain conditions, actually the indications for surgical treatment are always relative, not absolute. Consequently, with advances in the art and science of surgery, its proper scope broadens. The surgeon, as well as the referring physician, must always keep this point in mind in order to advise the patient wisely. For the physician to gauge the place of a surgical operation on the basis of its benefits and dangers twenty years ago or even ten years ago is manifestly unreasonable and unfair to the patient. The present study was undertaken to obtain information on the current risk of the operation of subtotal gastric resection, as performed for the relief of complications of peptic ulcer in a depleted, poor-risk group of patients. The series comprises 120 consecutive cases recently operated on by the senior author.

The Hoffmeister type of subtotal gastrectomy has been used almost exclusively, and the anastomosis has been of the antecolic, short jejunal loop variety. Actual measurements have shown an average excision of 80 per cent of the stomach. When the ulcer was duodenal, it was usually, but not always, excised. In the penetrating duodenal ulcer with extensive involvement of surrounding tissues and a pancreatic crater, the operation described by Allen has at times been employed with satisfaction.[1] Ether anesthesia by closed system and endotracheal catheter has been used, and early ambulation has been routinely practiced with the patients walking within twenty-four hours after operation. Penicillin has been used postoperatively and in a few cases streptomycin as well. Blood transfusion has been freely used during and after operation, not only in the acutely bled-out patients but in the nonhemorrhagic cases.

The indications for gastric resection in the 120 cases are shown in Table 1. The commonest finding was intractability to medical management, which usually meant penetration of the ulcer to such an extent as to involve neighboring structures outside the stomach or duodenum. In many instances, the ulcer had actually burrowed into other viscera. Often there were several of the so-called surgical complications of peptic ulcer present in the same patient. Thirty-four of the patients were suffering from acute massive hemorrhage and were operated upon within twenty-four hours after admission to the hospital.

Suspected malignancy	7
Recurrent bleeding	4
Obstruction	5

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo, Section on Surgery, May 6, 1949.

In each of these the red cell count was 2,500,000 per cu. mm. or less, or the total circulating red cell mass was 60 per cent, or less, of normal. The less seriously exsanguinated patients were not operated upon until they had recovered from the effects of hemorrhage, for a specific study of the merits of gastric resection for acutely massively bleeding ulcer was being carried out.

It is of special interest that during the same period of time, while 120 patients had gastric resection for the indications mentioned, 13 patients had gastric resection for supposedly benign gastric ulcer which turned out to be malignant. Since 42 of the 120 patients operated on for peptic ulcer had benign gastric ulcer, it follows that the incidence of unsuspected cancer was 13 out of 55 gastric ulcerations coming to operation, or 23.6 per cent. Of further interest was the fact that there were 47 patients during the same period of time hospitalized for perforation of peptic ulcer. Perforation is, therefore, somewhat less common than massive hemorrhage as a complication, for a control group of 30 cases of massive hemorrhage during the same period were not operated upon.

The average duration of symptoms of peptic ulcer in the 120 patients of the series was eight and eight-tenths years. Twenty-five of the group had had previous operations for peptic ulcer—in 12 instances suture of perforation. Twenty of the 120 patients were classified as chronic alcoholics, while in 13 frank malnutrition and avitaminosis were present. The weight loss, as averaged from the data obtainable with reasonable accuracy in 84 patients, was 14 pounds. Two patients were so depleted that ascitic fluid was present in the peritoneal cavity at the time of gastric resection; in both, convalescence was uneventful.

Shown in Table 2 is information to indicate associated diseases found in the series of 120 patients. The degenerative diseases, malnutrition, chronic alcoholism, and pulmonary tuberculosis were common. Since the patients were in

TABLE 3.—Age Distribution of 120 Patients Having Gastric Resection for Peptic Ulcer

	Age Distribution (Years)							
	10 to 20	20 to 30	30 to 40	40 to 50	50 to 60	60 to 70	70 to 80	80 to 90
Acute massive hemorrhage cases (34)	0	3	6	5	4	13	3	
Not acutely bleeding (86)	1	3	11	22	27	17	3	
Total	1	6	17	27	31	30	6	

the older age group, the high incidence of hypertensive cardiovascular disease was not surprising. Five patients had suffered one or more bouts of cardiac decompensation, and two showed signs of decompensation on admission to hospital. Four were taking digitalis when admitted; four were suffering from angina pectoris, and one had had coronary occlusion. Nine patients showed electrocardiographic changes denoting diffuse myocardial damage, and in seven cardiac enlargement on radiographic examination was pronounced. Four patients had systolic blood pressure above 200 at operation.

Of the 19 patients with pulmonary disease, the seven with active pulmonary tuberculosis were of particular interest. Despite the presence of cavitation, which was bilateral in one case, operation and anesthesia were well borne. In the group of patients with malnutrition and avitaminosis, as in those with chronic alcoholism, the peptic ulcers were found to be especially large, and the involvement of neighboring organs was often severe. In two of these patients ascites was present at the time of gastric resection. The miscellaneous associated diseases included a wide variety of lesions, such as carcinoma of the larynx, psychoneurosis (three patients), neurofibromatosis, epilepsy, and cholecystitis with cholelithiasis. No patient in the series had cirrhosis of the liver.

That the series of patients represented a wide distribution of age is shown in Table 3. However, the preponderance was in the older age group, and the average age for the entire group was fifty-one and one-half years. The oldest patient, a man of eighty-five years, gave a history of peptic ulcer going back for over twenty years. The youngest patient, eighteen years of age, had had four episodes of massive hemorrhage from duodenal ulcer since the age of sixteen. The fifth, sixth, and seventh decades showed the highest number of cases. The series is too small to warrant statistical conclusions, but it is notable that in the 34 patients acutely exsanguinated from hemorrhagic ulcer the average age was somewhat higher and a disproportionate number of patients were in the seventh decade of life.

With regard to laboratory data, interest centers chiefly in the group of patients admitted for acute massive hemorrhage. This group of 34 patients

met the following criteria of classification: (1) There had been gross bleeding into the gastrointestinal tract with attendant signs of cerebral anoxia within one week and (2) the admission red cell count was 2,500,000 per cu. mm. or less, or the total circulating red cell mass was reduced to 60 per cent, or less, of normal. These patients had blood replacement and gastric resection within twenty-four hours after admission. The average initial red blood cell count for the 34 patients of this group was 2,610,000 per cu. mm. The average for the nonhemorrhagic group was 4,250,000 per cu. mm., there being 72 observations recorded. The plasma protein concentration, as averaged from 30 hemorrhagic cases on admission, was 5.95 Gm. per 100 cc., and for 59 nonhemorrhagic cases the average value was about the same (5.92 Gm. per 100 cc.). The lowest plasma protein concentration recorded for the entire group was 4.0 Gm. per 100 cc.

As observed at operation 62.5 per cent of the ulcers were duodenal, 23.3 per cent were gastric, and 11.6 per cent were both gastric and duodenal. In one patient the site of the ulcer was not recorded, and in two patients the ulcer was marginal and based on gastroenterostomy performed years before. In 49 cases the ulcer showed penetration into the pancreas and in four penetration into the liver. Four patients had resection of jejunum and old posterior gastroenterostomy as well as gastric resection, and one patient with a gastrojejunocolonic fistula also had to have resection of the colon.

In considering postoperative complications in the series, as shown in Table 4, pulmonary atelectasis and infection were the commonest and occurred singly or together in 32 patients. In no instance were these complications fatal, and, as a rule, convalescence of the patient was retarded only slightly, if at all. In four cases there was enough bleeding to be noted in the nasogastric suction drainage during the first forty-eight hours after operation. In two instances there was temporary gastric retention following operation. There were two instances of wound dehiscence, four of wound infection, four of thrombophlebitis, and one of nonfatal pulmonary embolism.

TABLE 5.—MORTALITY FOR GASTRIC RESECTION IN 120 CONSECUTIVE OPERATIONS FOR COMPLICATED PEPTIC ULCER

Indications for Operation	Number	Deaths
Acute massive hemorrhage	34	5
Other surgical complications	86	0
Total	120	5

In Table 5 are shown mortality figures for the series. The five deaths were all in the group operated upon as a life-saving measure for exsanguinating hemorrhage. Brief abstracts of these five cases are included below. It should be mentioned that the mortality rate in a similar group of cases of massive bleeding treated nonsurgically was approximately twice as great.

Case Reports

Case 1.—S. P., a seventy-four-year-old man with a history of peptic ulcer of two years duration, was brought into the hospital unconscious from massive hemorrhage into the upper gastrointestinal tract. He had been vomiting blood for twenty-four hours. Blood pressure and pulse responded somewhat to transfusions, but the patient remained disoriented. He was operated upon within twenty-four hours after admission, and gastric resection was performed for a large duodenal ulcer penetrating into the pancreas and liver. The patient died the following day, and autopsy showed extensive hemorrhagic softening of frontal, parietal, and occipital lobes and basal ganglia.

Case 2.—J. K., a fifty-six-year-old man with a history of ulcer dyspepsia of four months duration, came to the hospital after four days of exsanguinating hemorrhages into the upper gastrointestinal tract. He was not in shock when admitted. After transfusion therapy he was operated upon, and a duodenal ulcer with pancreatic penetration was excised with subtotal gastrectomy. The immediate postoperative course was satisfactory but the patient died on the sixth postoperative day after an episode of hematemesis. Autopsy was not performed.

Case 3.—W. K., a sixty-five-year-old man, was admitted to the medical service for arteriosclerotic heart disease with decompensation. Five days after admission he had severe hematemesis and melena and went into collapse. At operation he was found to have a gastric ulcer with pancreatic adhesion, and gastric resection was performed. His postoperative course was excellent until the third day when he died suddenly while being examined. He had been digitalized prior to operation. No autopsy was performed, but death was attributed to coronary artery disease.

Case 4.—M. P., a sixty-one-year-old man with severe hunchback deformity, was admitted in hemor-

In each of these the red cell count was 2,500,000 per cu. mm. or less, or the total circulating red cell mass was 60 per cent, or less, of normal. The less seriously exsanguinated patients were not operated upon until they had recovered from the effects of hemorrhage, for a specific study of the merits of gastric resection for acutely massively bleeding ulcer was being carried out.

It is of special interest that during the same period of time, while 120 patients had gastric resection for the indications mentioned, 13 patients had gastric resection for supposedly benign gastric ulcer which turned out to be malignant. Since 42 of the 120 patients operated on for peptic ulcer had benign gastric ulcer, it follows that the incidence of unsuspected cancer was 13 out of 55 gastric ulcerations coming to operation, or 23.6 per cent. Of further interest was the fact that there were 47 patients during the same period of time hospitalized for perforation of peptic ulcer. Perforation is, therefore, somewhat less common than massive hemorrhage as a complication, for a control group of 30 cases of massive hemorrhage during the same period were not operated upon.

The average duration of symptoms of peptic ulcer in the 120 patients of the series was eight and eight-tenths years. GASTRIC MALIGNANCY

JOHN J. MORTON, M.D., Rochester, New York

(From the Department of Surgery, University of Rochester School of Medicine and Dentistry)

WHAT the medical profession needs is a simple test to determine abnormal gastric physiology. If such a test were available, we could assemble groups of those patients with an increased tendency toward the development of gastric malignancy. We would weight these groups as heavily as possible in our favor, selecting those patients who had conditions which in the past had preceded the development of malignancy. We would start with the age factor; then the sex factor; the presence of atrophic gastritis, gastric ulceration, or pernicious anemia; the absence of free acid or a diminished gastric acidity; and those showing occult blood in the stools. Since 93 per cent of gastric malignancies occur after forty years of age we would begin at this age level.[1] We would choose twice as many men, since in gastric cancer incidence males outnumber females by 61.6 per cent to 38.4 per cent.[2] All gastric ulcerations would be carefully observed, since 10 per cent turn out to be ulcerating cancers.[3] Although pernicious anemia patients constitute only 5 per cent of the carcinomas of the stomach, it would, nevertheless, be important to follow this group carefully.[4] The hypoacidity or anacidity groups are in more jeopardy than people with normal acid values. Those with low or absent hydrochloric acid constitute about 30 per cent of the people over fifty years of age.[5] Comfort and coworkers have demonstrated that there was achlorhydria or hypochlorhydria in over half of a series of patients who subsequently developed gastric cancer.[6] Stout noted that, from the third decade on, mucosal atrophy was encountered with increasing frequency.[7] All these factors add up to an increased liability for the development of malignancy. If the medical profession could get these individuals together and follow them periodically, earlier recognition of gastric malignancy might be possible.

Atrophic gastritis can be diagnosed in life only by gastroscopic examination. For practical purposes this does not make a convenient screening mechanism. Pernicious anemia can be diagnosed by a good blood examination. All such patients should be known in any general hospital record room. Gastric ulceration can be demonstrated by x-ray studies. This is not generally available for large group studies. When normal people over fifty years have had mass survey by this method, only one in a thousand showed positive evidence of malignant change. This is a time-consuming, expensive method with little return for the effort expended. Absence of hydrochloric acid or diminished amounts of it require passage of a tube and chemical study. For these reasons it is not a good mass study tool. We have endeavored to simplify the mechanisms for determination of the acid content of the stomach because we think it is the best lead that we have at present for detecting potential gastric cancer victims. If determination of the gastric acidity were made on all patients over forty years of age in our general hospitals, we would soon build up a group of people with low or absent gastric acidities. This would require some extra effort, but it might be much more valuable than some of the other routine laboratory tests.

The symptoms and signs of early gastric malignancy are minimal. By the time the symptoms develop the lesion is advanced. We cannot expect to make a diagnosis in time for curative therapy under such circumstances. The more pronounced symptoms are epigastric pain, vomiting, loss of weight, loss of appetite, and weakness. These mean well-established disease. The more minor complaints deserve our careful scrutiny. Fullness, gas, and discomfort after eating may have important significance. Loss of energy and a distaste for food should arouse suspicion. Alvarez emphasizes that something is radically wrong whenever a man or woman, after a lifetime of good health, begins to suffer with epigastric pain or discomfort, or a feeling that food is remaining too long in the stomach.[8] "Indigestion does not begin after the age of forty years," according to Ogilvie, and it should be followed till proved innocent.[9] This means turning our entire battery of diagnostic tests into action. X-ray study should consist in more than simple fluoroscopy, as even the most experienced radiologist may overlook the small lesion. This is the important lesion to detect. Consequently, "prolonged, painstaking fluoroscopy, 'spot' films, and roentgenograms in several positions" are requisites, according to Rigler.[4] Gastroscopy should be used as well whenever possible. Tests for gastric acidity should be done, probably on the old-fashioned test meal basis rather than after whipping up the acid glands by histamine.

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo, Section on Surgery, May 6, 1949.

rhagic shock gasping for breath. He had been vomiting blood and passing tarry stools for twenty-four hours. The response to transfusion therapy was poor. He died seven hours after gastric resection without regaining consciousness. In the gastric specimen there were multiple prepyloric ulcers containing open vessels.

Case 5.—A. L., a sixty-year-old woman with a ten-year history of peptic ulcer, was admitted, bled-out and showing air hunger. She had been passing blood by rectum and vomiting blood over a three-week period. At operation a posterior wall duodenal ulcer with pancreatic crater was found. The ulcer-bearing area of the duodenum was excised, and gastric resection was performed. She died three days after operation with signs of bronchopneumonia and peritonitis. No autopsy was performed.

Summary

A study has been made of the risks of gastric resection in a group of 120 consecutive complicated cases of peptic ulcer; the evidence for classifying the patients as poor-risk cases is analyzed, and the morbidity and mortality findings are presented. It seems profitable to conclude that adequate ulcer-correcting gastric resection can now be performed with low risk even in patients presenting locally and generally unfavorable conditions.

Discussion

Herman Pearse, M.D., *Rochester.*—Dr. Stewart is to be congratulated in attaining so low a mortality as 4 per cent in such a poor-risk group of patients subjected to a major surgical procedure. This extension of operability, in spite of the degenerative diseases of old age and complications from the primary disorder, is prevalent in all of surgery today. The resident surgeon now calmly proceeds under circumstances that would have made the senior attending physician shudder twenty years ago. I doubt if this is due to better surgical skill. Rather, it comes from improvement in the ancillary measures used before, during, and after the operation. These are largely responsible for our smaller mortality and greater scope of activity.

The appreciation of the need to correct anemia, hypoproteinemia, dehydration, demineralization, and avitaminosis; the strengthening of cardiovascular and renal function; the improvement in anesthesia; the avoidance of shock by blood replacement, and the prevention of postoperative complications by antibiotics, rebreathing, hydration, gastric suction, and early ambulation are the measures that have extended the scope of surgery.

Hence, this report of Dr. Stewart's is very timely, for it demonstrates the degree of safety with which major operations may now be done by skilled surgeons on poor-risk patients.

ANTIBIOTIC DRUG PROVES VALUABLE FOR SKIN DISEASE

Successful use of an antibiotic drug, bacitracin, for impetigo and other skin diseases is reported in the September 17 *Journal of the American Medical Association.* Bacitracin is thought to be especially valuable because it apparently causes few allergic reactions, say Drs. Jack L. Derzavis of Georgetown University School of Medicine, Washington, D.C., and J. Sidney Rice and Louis S. Leland of the U.S. Army Medical Corps, Washington, D.C. In contrast, use of sulfa drugs and penicillin for skin diseases has the drawback that some patients become hypersensitive to these substances which they may need later for severe infections, such as pneumonia.

To determine human sensitivity to bacitracin, the doctors made patch tests of 150 adults by applying a small amount of the drug to the skin for 48 hours. All of the tests were negative for reaction to bacitracin. A fortnight later, 50 of these same persons were retested by the patch method on the same site for another 48 hours. All test sites were again normal after the patches were removed.

"These results seemed indicative of low allergenicity and were subsequently corroborated by the occurrence of only one case of dermatitis of the contact type among the 138 patients subsequently treated with bacitracin ointment," the doctors point out. Only skin diseases which respond well to treatment with penicillin and the sulfa drugs were treated with bacitracin. Of the 138 patients, 128 were cured by the newer antibiotic drug, five were improved, and only five failed to improve.

Results against contagious impetigo are especially noteworthy. Many of these eruptions were cured in 48 hours after treatment with bacitracin was begun.

TABLE 1.—MORTALITY FOLLOWING SURGERY IN SOME SERIES

	Operability (Per Cent)	Resectability (Per Cent)	Mortality (Per Cent)	5-Year Survival (Per Cent)
Welch and Allen, Massachusetts General Hospital, 1941–1946	75.0	50.0	3.0	7.0
State, Moore, and Wangensteen, University of Minnesota, 1945–1947	88.0	80.0	3.8	6.6
Maimon and Palmer, University of Chicago, 1946[20]	83.5	52.1	16.3	7.4
Mayo Clinic, 1948	...	53.8	5.8	...

hitherto hopeless neoplasms. The technical advances in the suturing of the esophagus to stomach and the more adequate pre- and postoperative handling have cut the mortality rates as well.

It does not seem possible to improve the technical approach to resection to any great extent. The hope for better results must rest on getting the patient to surgery at an earlier stage. Hence, a mass screening test of a simple type is highly desirable.

Surgeons have increased their operability for gastric cancer. Resectability has also been extended including total gastrectomy when indicated. The mortality following surgery has been consistently whittled down till it is now below 10 per cent in many hospitals (Table 1). In some centers it is below 5 per cent. There are many more patients who live from three to five years after resection, and the five-year survival rate is over 7 per cent in some clinics. Palliative operations rarely prolong life, but the removal of the growth is worth a great deal in the comfort that it gives. If the nodes are involved, the prognosis is much poorer. Even in those cases where no node involvement is demonstrated, a number will be found to have direct extension through the lymphatics of the stomach. Sections should be taken from the upper end of the resected stomach to determine this point. In other instances there is invasion of the blood vessels, demonstrated in the studies of Warren and coworkers.[17]

The largest number of five-year survivals in the gastric sarcomas is in the lymphosarcoma group.[18] The prospect for cure in these patients is somewhat better than it is for those who have carcinomas. Both the resectability rate and the five-year survival rate are somewhat higher than for gastric carcinoma. The malignant lymphocytoma type (small round cell sarcoma) is more responsive to radiotherapy than the reticulum cell variety. The fact that four out of six patients with Hodgkin's disease of the stomach were living six to eight years after partial or complete gastric resection indicates that this disease may not always be multicentric in origin.[19]

We must continue to treat gastric malignancies with the best tools that we have until something better is discovered. Radical surgery seems to be our main reliance at the present. Consequently, it behooves us to get the patients to the surgeons when there is still a chance for cure. We look forward to better forms of treatment in the near future. Meanwhile let us screen the aging population as carefully as we can to pick out in time those who may become afflicted with gastric malignancies.

Discussion

William A. Cooper, M.D., *New York City.*—Dr. Morton has covered the subject completely, and I would like to endorse everything he has said. The cure for gastric cancer is available, and each year some cases are salvaged by proper surgery. This salvage rate is low, primarily because our diagnostic methods are cumbersome, expensive, and imperfect.

For several years Dr. Papanicolaou and I have been working on the cytology of the gastric juice in an effort to diagnose gastric cancer pathologically. The normal gastric juice contains rather few cells, most of which are blood elements (red cells, lymphocytes, and polymorphonuclears) and desquamated squamous cells from the upper digestive tract. Occasionally cells are found from the respiratory epithelium. Rather few cells are seen from the gastric mucosa, so that finding such a group is rare.

In patients with gastric cancer abnormal cells may be recovered. They vary in size and shape, and the nuclei are bizarre or may be multiple. The finding of just one such abnormal cell may reasonably confirm the diagnosis.

In several hundred cases in which this method has been used, about 50 per cent of the gastric cancer cases failed to show such cells. These were missed

Search for exfoliated cells may be diagnostic if performed before the material is digested. It is essential that an experienced cytologist review the cells to differentiate them from the nasal, bronchial, and esophageal cells which may be present following tube passage. Papanicolaou and Cooper initiated this type of study which is being pursued widely at present.[10] The combination of radiography and the Schmidt camera may diminish the radiation dosage danger and give a simpler screening mechanism. This has been the experience at Johns Hopkins and at the Roswell Park Memorial Institute in Buffalo.

If such a program is followed, the chances of finding gastric cancer earlier are good for the middle-aged and older people. It ignores the cancers and other malignant gastric tumors which arise in children and young adults. Goldstein recorded from the world literature a large number of gastric carcinomas in these age groups.[11] It is surprising to find cases of gastric cancer as early as the tenth day of life.[12] King collected 40 cases from the literature for the first two decades of life.[13] Phillips found 90 cases of gastric carcinoma and six of gastric sarcoma in persons less than thirty years of age in the Mayo Clinic records to the time of his review.[14] Altogether, this seems like a considerable number, but it amounts to slightly over 1 per cent of gastric cancers.

The same may be said for malignant tumors of the stomach, other than cancers. These sarcomas constitute between 2 and 3 per cent of gastric malignancies. Differential diagnosis from carcinoma of the stomach is almost impossible. For practical purposes any tumor of the stomach should be regarded as cancer until proved otherwise. This means diagnosis by microscopic examination. The sarcomas tend to occur in an earlier age group; their duration appears to be longer; the late symptoms are less severe except for the hemorrhages which may be profuse, especially with the leiomyosarcoma type. Since about 64 per cent of the sarcomas are lymphosarcomas, the spleen may be enlarged in about 10 per cent of the cases. Pathologic examination will show that fibrosarcomas stand next in frequency and that leiomyosarcomas and angiosarcomas constitute most of the remaining lesions. Hodgkin's disease and leukemias, as well as some rarer forms, may also involve the stomach.

The benign tumors, especially the leiomyomas, are regarded as definite threatening lesions by some surgeons who urge their thorough removal for good prophylaxis.[15] The gastric polyps should be placed in the same category. From the medical standpoint, Berry and Cole found that prompt relief from gastric mucosal atrophy could be obtained by proper nutritional substances added to their treatment.[16] Liver extract, vitamin B complex, and nicotinic acid were employed with relief of symptoms and resumption of a normal appearance of the gastric mucosa on gastroscopy.

The question regarding the proper management of the gastric ulcer patient has been well stated by Alvarez and more recently by Allen.[8,3] Alvarez wrote, "After ten days of dieting, the crater should show marked shrinkage, and in twenty days it should be hard to find. If it does not show signs of healing, it may yet be benign, but it is dangerous to go on with medical treatment. If the lesion continues to grow in size, operation must be done immediately."[8] Allen advocates observation in the hospital and medical treatment if (1) the patient is young and the lesion acute, (2) if the lesion is under 1 cm. in diameter, and (3) if it is on the lesser curvature or on the anterior or posterior wall.[3] If the healing is complete under medical treatment, repeat the studies one month later. If the healing is not complete within one month, surgery should be done. Immediate surgery is indicated (1) if the ulcer is of short duration and the patient is over fifty years of age, (2) if the ulcer is over 2.5 cm. in diameter, (3) if there is no free hydrochloric acid, (4) if the ulcer is on the greater curvature or in the prepyloric region, and (5) if the ulcer is chronic, recurrent, and on the lesser curvature. If this advice is followed, the 10 per cent of ulcerating cancers of the stomach will be picked up in their early stages.

The treatment of gastric malignancy is surgical. If the lymphosarcomas could be diagnosed beforehand, a trial of radiotherapy might be used in those cases which showed a favorable response. This is rarely possible. The surgery must be radical in type in order to remove the regional nodes in the pyloric region, along the lesser curvature, and about the hilar region of the spleen in the fundic region. Total gastrectomy would be the ideal operation for complete "bloc dissection." The cure rate is not sufficiently greater than that of subtotal gastrectomy to warrant the risk of the higher mortality rate for total gastrectomy. If this discrepancy can be obviated, there is no doubt that total gastrectomy is the more thorough operation.

The operability has been extended to include removal of adjacent organs with the stomach when involved by the growth. Direct extension to the transverse colon, to the left lobe of the liver, or to the pancreas no longer constitutes an obstacle to surgery. No patient should be denied the right of exploration, because many times there is more to be accomplished than is thought possible. The transthoracic access to the cardiac growths has made it possible to remove these

TRASENTINE-PHENOBARBITAL

a powerful antispasmodic ... with selective action avoiding undesirable side effects

Effective relief of visceral spasm is generally obtained with Trasentine or Trasentine-Phenobarbital. By its selective action, Trasentine avoids the undesirable side effects of dryness of the mouth and pupillary dilatation frequently produced by belladonna or atropine. These advantages have caused physicians to prescribe more Trasentine and Trasentine Phenobarbital than any other brand of antispasmodic.

Average adult dose is one or two tablets 3 or 4 times daily as required.

TRASENTINE-PHENOBARBITAL — Tablets (yellow) contain 50 mg. chloride with 15 mg. phenobarbital, in packages of 100 and

TRASENTINE — Tablets (white) of 25 mg. in bottles of 100, of 100 mg. and ampuls of 50 mg.

diagnoses. There were less than 1 per cent false positives. The method is still in its research phase, and we hope to discover better methods for obtaining cells that will make diagnosis possible. One of the encouraging features is that some of our best specimens have been recovered from some of the smallest tumors. If we can perfect the method and obtain such material from 80 to 90 per cent of cases with gastric cancer, a new and valuable screening method will become available.

Until that time when an adequate diagnostic procedure for early gastric cancer can be developed—and I believe that it will be—we must rely on vague clues and a variety of imperfect aids. The discovery of precursor groups such as pernicious anemia, achlorhydria, and, possibly, gastric ulcer is helpful in focusing attention on these groups for particular scrutiny, but the major responsibility for the discovery of early gastric cancer, for many years to come, will lie primarily with the clinician. The family doctor who first listens to the patient's complaints holds the key position in gastric cancer. It is he, rather than the specialist, that has the opportunity to apply the various diagnostic aids early in the course of the disease.

Sidney A. Gladstone, M.D., *New York City.*—For about one year we have been using suitable sponge to obtain from accessible sites small particles of tissue for microscopic examination in the diagnosis of cancer. Our efforts have been confined for the most part to lesions and sites which we could see and upon which we could rub a sponge under direct vision. Within the past month we have introduced sponges into the fasting stomach of patients, either as a series of sponges on braided silk or as a string of sponges wound spirally around the lower end of a Levine stomach tube. In a series of 12 cases there were two with proved cancer of the stomach. In each of these, particles of cancer tissue were found on microscopic examination of the sponges. In the third case a patient fifty years of age with a two-year "ulcer" history, complaining mostly of loss of appetite and slight weight loss, was examined by us by means of stomach sponge biopsy. The microscopic examination of the sponges indicated the presence of carcinoma which was confirmed by operation performed as soon as the diagnosis was made.

This type of study is at its beginning, and many cases must be studied before the technic can be crystallized and the results evaluated. It may be said at this time, however, that the method of stomach sponge biopsy provides, for examination, small particles of more or less viable tissue rubbed off ulcerating surfaces. This material, in contrast to the partly digested cells of the gastric contents, is morphologically well preserved and permits of easy microscopic recognition.

PRIZE ESSAYS

The Merrit H. Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York, May 8, 1950, in New York City.

The Lucien Howe Prize of $100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merrit H. Cash Prize of $100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed:

Essays shall be typewritten or printed with the name of the prize for which the essay is submitted, and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device, and containing the name and address of the writer.

If the Committee considers that no essay or contribution is worthy of a prize, it will not be awarded.

Any essay that may win a prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented not later than February 1, 1950, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York 17, New York.

...LECTION OF OPERATION FOR CARCINOMA OF THE LOWER ...RTION OF THE COLON AND RECTUM

...RLES W. MAYO, M.D., Rochester, Minnesota

...m the Division of Surgery, Mayo Clinic)

...OR purposes of clarity and understanding, a discussion of this nature must be kept within ...ecific bounds. Consequently, I shall confine ...yself here to malignant lesions that are situated ...thin 20 cm. of the dentate margin of the anus. ...or convenience of presentation and because, in ...y opinion, the distance from the anus that a ...sectable lesion is situated is one of the most ...portant factors which influence the type of ...rgical procedures to be selected, I have divided ...his 20 cm. of bowel into four parts of 5 cm. each. ...This statement is made advisedly, because there ...still are those who sincerely believe that a prop...erly performed combined abdominoperineal resection is the operation of choice for all carcinomas which are situated within this limit of distance; that is, for lesions that have passed beyond the stage at which they can be dealt with safely by fulguration.

The objective of the surgeon is to get beyond the reaches not only of the primary growth but also of its metastatic spread. If the operative procedure selected fails to accomplish this, the result is only palliative. The theory that prompts those who advocate the most radical of resections in all instances has the semblance of practicality in that, they argue, it is impossible to predetermine whether there is lymphatic involvement and, if so, whether the spread will be upward, lateral, or retrograde.

Opinions gradually have been influenced by special studies relative to lymphatic spread. These studies, although confirming the great importance of upward spread, also have led to proper evaluation of lateral and retrograde lymphatic involvement. Although many investigators have contributed to the development of these particular aspects of the field, great credit must go to Gilchrist and David, Coller, Kay and MacIntyre, Glover and Waugh, Dafoe, and Kirklin, Dockerty, and Waugh, for their careful work on the subject.[1-6]

The Time Factor

Time, however, remains the greatest single factor that influences the final result in the individual case of malignancy: the time between initiation and discovery of the malignant process, regardless of cause, and the time between discovery and adequate removal of the lesion. At some time, regardless of the patient's age and heredity and the location, grade, or type of malignant lesion, the lesion is curable; it is confined to the areas under discussion in this paper and if it can be discovered and removed while it is still confined locally.

The first point to which I would draw your attention, therefore, is that any time that is allowed to elapse between the finding of a malignant lesion and initiation of preparation of the bowel for adequate surgical treatment may be time tragically wasted. In the interest of the patient, let us hear no talk such as, "I have a patient with cancer of such and such waiting for me to do when I get home," or "I let the patient go home to settle up his affairs; he will be back in two weeks." This interval in treatment can well be the difference between palliation and cure.

Other Important Factors

In addition to time, many other important factors enter into the picture to hasten penetration and spread. The grade of malignancy, according to Broders' classification, is perhaps the next most important consideration.[7] There is now an abundance of proof that the degree of glandular involvement increases in direct proportion to the grade of malignancy. We know, too, that patients in the younger age groups have a poorer prognosis, as a whole, than do members of the older age groups, regardless of the grade of the lesion. Another point is that the greater the obstruction, the poorer the prognosis. When there is complete obstruction, the five-year survival rate is twice as poor as it is when obstruction is not present.[8] When venous involvement has been found by pathologic study of the removed specimen, 95 per cent of the patients concerned will succumb within five years, as demonstrated by our follow-up studies.

Actually, it is the summation of all factors determined preoperatively and at the time of operation, by both the surgeon and the surgical pathologist that influences the surgeon's judgment as to what technic he shall employ and the

Presented, by invitation, at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo, Section on Surgery, May 6, 1949.

extent of resection indicated in the individual case.

Site of Lesion and Choice of Operation

The situation of a cancer, if it is not outweighed by one or more of the aforementioned factors, is of greatest importance in determining the type of surgical procedure to be performed, and it is the one consideration I shall stress on the basis of evidence that has been developed and is developing regarding lymphatic spread. Perhaps I best can express my own attitude toward cancer of the rectum and lower portion of the sigmoid by stating that before operation I have all patients with such surgical conditions prepared, mentally and physically, for the establishment of a permanent colonic stoma and one-stage combined abdominoperineal resection. I am sure that if abdominal exploration justifies it, I will, in fact, perform one-stage combined abdominoperineal resection in some cases, namely, those in which a resectable lesion involves, in whole or in part, the first 5 cm. of the rectum above the dentate margin. For lesions situated above this segment of rectum, although I have anticipated that I may perform one-stage combined abdominoperineal resection, I hope I may find, on abdominal exploration and after mobilization of the lesion, that resection and re-establishment of the continuity of the bowel can be performed safely.

Preservation of the Anus

It is only natural that one of the great concerns of a patient should be that the normal anal outlet and its control be preserved. It is the surgeon's responsibility to see to it that the anus is not sacrificed unnecessarily. A comfortable and productive life is compatible with a permanent and well-made abdominal colonic stoma, but it is difficult to convince oneself or one's patient that an unnecessary colonic stoma is justified.

Rectum Above the Dentate Margin

First Five Centimeters above the Dentate Margin.—For carcinomas that involve the first 5 cm. of the rectum, in whole or in part, an extensive resection should be performed in the light of present knowledge regarding upward, lateral, and retrograde glandular involvement.

Barbosa, Waugh, and Dockerty, in a study of 105 cases of low-lying rectal and anal adenocarcinomas, concluded that the prognosis for these lesions is poorer than for those situated higher.[9] Gilchrist and David, in a report of their cases, also have indicated that a poorer prognostic result obtains in low-lying rectal lesions.[1,2] It has been demonstrated that such carcinomas spread not only upward but also laterally along the lymphatic vessels. Lateral spread usually does not occur in the levator muscle bundles themselves, but in the lymphatic vessels of the fascial planes of the levators. Retrograde spread is a late sequela and is the result of lymphatic blockage above and to the sides. It has been this concept, plus the feeling that combined abdominoperineal resection is, as a rule, not sufficiently radical for the low-lying rectal carcinomas, that have motivated Dixon for years to apply the technic of colostomy for such lesions and, later, radical posterior resection, with the patient in the Kraske position, or the two-stage combined resection with removal of the superior hemorrhoidal vessel, a single-barrel colostomy, inversion of the rectal stump, and, later, posterior resection.[10]

The weight of evidence for dealing with malignant lesions in the first 5 cm. of the rectum that require surgical treatment, whether resection is undertaken with the expectation of cure or for palliation only, shows that a permanent colonic stoma should be created and wide resection of the rectum should be carried out. The method I prefer is one-stage combined abdominoperineal resection. The reasons for this preference are that the operation can be as radical as any other type of procedure, the operative mortality rate is as low as that of other methods, or lower (a review of 1,097 cases in which operation has been performed at the Mayo Clinic from 1940 through 1948 revealed an over-all hospital mortality rate of 3.6 per cent), and finally, the operation is performed in one stage, so that the time the malignant lesion remains in the body is shortened and the morbidity and expense to the patient are minimized.

The so-called pull-through operation, with preservation of the sphincter muscle, should not be attempted for malignant lesions at this level, no should an attempt be made to perform low anterior resection and anastomosis. According to our pathologic findings, approximately half of the malignant lesions of the rectum, regardless of location, have metastasized to lymph nodes at the time of resection. For half of the patients, therefore, knowing the pathways of such spread, I consider it imperative that radical excision be performed for the low rectal lesions under discussion. Dukes is correct, of course, in stating that the life expectancy for patients from whom unmetastasized carcinoma of the rectum has been removed is good, no matter in what location it may have been.[11]

Six to Eleven Centimeters above the Dentate Margin.—I would call to your attention again the fact that the divisions of the bowel that have been made for this discussion are arbitrary. I would remind you, too, that measurements of distance for lesions in the rectum, even though designated

by the proctoscope, are not without a degree of error. Yet some standard must be accepted, and it would seem that, on the whole, the judgment of the physician at the time of proctoscopic examination best fits the needs.

The level of peritoneal reflection from the anterior surface of the sigmoid, to the vagina in the female and to the bladder in the male, varies in each case; it is estimated to range from 5 to 10 cm. or more. All the rectum and the lower posterior portion of the sigmoid are devoid of peritoneum.

The segment of rectum from 6 to 11 cm. from the dentate margin is that about which there is greatest disagreement and contention from the standpoint of operation of choice. It is for lesions within this area, essentially, that surgeons begin to form their individual preferences of technical procedures, each with his own major or minor variations. In general, the methods divide themselves into the following categories: (1) one-stage combined abdominoperineal resection (Miles); (2) one-stage combined abdominoperineal resection, with preservation of the sphincters or so-called pull-through operation (Babcock-Bacon); and (3) low anterior segmental resection with primary anastomosis, with or without concomitant colostomy.

This is the most important area for our consideration because, as stated before, there are those who unequivocally believe that, in fairness to the patient, one-stage combined abdominoperineal resection and permanent colostomy constitute the only operation to be considered for malignant lesions in any portion of the rectum. Prior to World War II, I too was of this opinion, but since then I have been influenced by the careful studies that have been made of lymphatic spread, and I have increasingly adopted low anterior segmental resection for lesions of the upper portion of the rectum, concerning which more later.

However, it is my opinion that for lesions situated in whole or in part within the limit of 6 or 7 cm. from the anal margin, the percentage of cases in which a Miles type of one-stage combined abdominoperineal resection should be performed increases. In other words, it is not that I do not consider the Miles type of combined and abdominoperineal resection a valuable operation, and it is not that the percentage of so-called cures will not be high, all factors considered. It is simply a question of whether or not there is available a procedure as radical as necessary to obtain the same end results in selected cases as those obtained from the abdominoperineal resection and, in addition, a procedure which is accompanied by an equivalent hospital mortality rate and lowered morbidity rate and still leaves the patient with a normally controlled and functioning anus.

I have found that those who are so adamant in their stand against the low anterior segmental resection, even for selected lesions in this region, are of the same mind also in regard to the one-stage combined abdominoperineal resection with preservation of the anal sphincters. I also have observed that those who most criticize that type of operation have seen it done the least often. To have seen recurrences follow the modified Hochenegg operation is no justification for the contention that the operation has no place in rectal surgery for cancer. There is no colon surgeon, no matter how excellent his judgment is or how skilled he is technically, who has not seen more recurrences than he expected in his own well-treated surgical patients.

For lesions in this particular area of the rectum, I think the so-called pull-through operation, well performed, does have a place. From my experience with it, I am equally of the opinion that it is not an operation for me to perform. Waugh at the Mayo Clinic, Babcock and Bacon in Philadelphia, and other accomplished individual surgeons with extensive series of operations performed by their own methods are in a better position than I am to judge the merits and shortcomings of this particular procedure. They perhaps would employ it in cases in which I most often would select low anterior segmental resection or, more rarely, the Miles combined abdominoperineal resection.

In the presence of lesions of the upper part of the rectum we are confronted with four schools of thought:

1. Combined abdominoperineal resection;
2. That which advocates resection with end-to-end anastomosis and concomitant transverse colostomy;
3. That which advocates resection and anastomosis, without performance of colostomy; and
4. That which advocates resection, sometimes with and sometimes without performance of colostomy.

Essentially, all remarks or writings in medicine and surgery reflect principally the thoughts and opinions of the author. Here, then, I shall present my own ideas about anterior segmental resection.

I have become more and more impressed with the advantages of anterior segmental resection for the majority of cancers of the upper portion of the rectum, as I have seen them and have studied the results obtained by those who have performed this operation more times than I have. In a study which I reported of two series of 100 consecutive cases each, one not involving the concomitant performance of colostomy and the

other including this procedure, the over-all hospital mortality rate was 4.5 per cent, counting all deaths from all causes. Dixon has studied his cases of performance of anterior segmental resection from the standpoint of prognosis, and the results are comparable to those obtained from combined abdominoperineal resection, as far as three-year and five-year survival rates are concerned.[10]

It has been stated previously that all patients scheduled for operation for cancer of the rectum and lower portion of the sigmoid are prepared preoperatively for combined abdominoperineal resection and are advised that this procedure may be needed. The decision as to the adoption of that procedure or of low anterior resection is not made until the lesion has been mobilized and the abdominal part of the operation has been performed, just as for combined abdominoperineal resection. If, at this point, conditions are found to be such that the rectum and its posterior and lateral tissues can be transected at a point at least 2 cm. below the lower border of the lesion and the remaining portion of the sigmoid can be mobilized to assure an accurate anastomosis without tension, then I select end-to-end sigmoidorectostomy as the operation of choice. As we now see them, in not more than 1 per cent of cases does retrograde spread extend more than 2 cm. below a lesion at this level. It is important to open the resected portion of bowel on removal to determine the distance from the lesion to the lower line of transection. If there is any question from any standpoint when the pathologic report is received, the rectum can be closed and the surgeon can proceed with the operation as a combined abdominoperineal resection.

If the colon has been well prepared from the viewpoint of cleanliness by irrigations and by the efficient use of available chemotherapeutic agents, clamps are not necessary in accomplishing the anastomosis. I use interrupted cotton sutures in the outer coats of the bowel and running catgut sutures in the mucosa. At the conclusion of the operation, after retroperitoneal drainage has been established and the drains have been brought out through the lower angle of the low left rectus incision, the anastomosis is extraperitonealized, and when the abdomen has been closed, the anus is dilated thoroughly. A tube is not inserted in the rectum past the site of the anastomosis and left in place, colostomy is not performed, and the use of the Miller-Abbott tube is a rarity.

More than three fourths of the patients treated by this method are able to leave the hospital within two weeks and to return home within three weeks after the date of the operation. This is a most decided material saving to the patient, both from the standpoint of the financial aspect and that of preservation of the anus.

Eleven to Sixteen Centimeters above the Dentate Margin.—At this distance, a lesion is still within the range at which many surgeons believe that the Miles type of operation is almost invariably indicated. Rankin recently has stated that one-stage combined abdominoperineal resection (Miles) is the operation of choice for all malignant lesions situated below a line 2 inches above the peritoneal reflection.[12] For lesions lying in this area or extending into it from above, I now, with few exceptions, perform low anterior resection with sigmoidorectostomy, just as described in the immediately preceding section of this paper.

For adequate surgical treatment there would seem to be little to be gained by performance of a pull-through operation for carcinoma at this level, considering the ease with which the surgeon can reach at least 2 cm. or more below the lower margin of such lesions.

Sixteen to Twenty-one Centimeters above the Dentate Margin.—Lesions situated at this level do not provoke grave controversy as to treatment; rather, there is a great concord of surgical opinion in this respect. With advancing progress in the methods of preparing the colon for operation and the application of the efficient antibiotic agents now available, extraperitoneal or modified Mikulicz operations are being applied less and less. Most surgeons now employ resection and primary anastomosis. There are, however, surgical points at this level, just as below, which must be kept in mind. These points include wide resection of the mesentery with removal of tissue well above and below the lesion, excision of the superior hemorrhoidal vessels after high ligation, and creation of an accurate anastomosis without tension. One more point which I stress is thorough dilatation of the anus.

Even those surgeons who formerly advocated and performed one-stage combined abdominoperineal resection for lesions at this level have abandoned it in favor of one-stage resection and primary anastomosis, although all surgeons have not accepted this without the concomitant performance of transverse colostomy.

Comment

It is encouraging to note that surgery of the colon and rectum is not a static field. Definite advances have been made in all its branches, to the benefit of the patient. To the chemotherapeutic agents now employed, to a better understanding of lymphatic pathways from the various levels, to improved anesthesia, and to technical developments to aid the surgeon goes great credit in lowering mortality and morbidity rates and lessening the unnecessary sacrifice of tissue. The

anus must be sacrificed when it should be, but it is a precious physiologic asset and certainly should be preserved when this can be done without unduly risking the "long-pull cure" hoped for by the patient and the surgeon.

Early diagnosis of lesions of the colon still is the great field for medical progress, for it is in the treatment of premalignant or early localized malignant processes that we can serve the patient best. In this connection, it is of value to point out that in a series of more than 1,000 proctoscopic and sigmoidoscopic examinations performed at the Mayo Clinic on patients who had had no signs or symptoms to indicate the need for such an examination, polyps that required fulguration were found in almost 10 per cent of the cases. I am convinced that this examination is a "must" for anyone undergoing a complete physical examination. If polyps are found and are properly treated, much grief will be saved many people later in life.

Cancer of the rectum or colon, diagnosed early and properly treated surgically at an early time, is curable. As Professor Charles A. Pannett, of England stated, "I have come to feel that scientific advance can be made only if we regard our contemporary beliefs as always wrong, or at most only half truths."[13] Certainly we must agree that an open and thoughtful mind is essential to medical progress.

Discussion

John Burke, M.D., *Buffalo.*—We will all agree that an ideal operation for carcinoma at any level of the gastrointestinal tract will be able to restore continuity and at the same time give assurance of complete cure. Most procedures, unfortunately, must compromise one or the other of these objectives. It is obvious that the cure factor is by far the most important. At the same time, we continue to strive toward restoration of the normal physiologic pattern. Whether or not we belong to the school which feels that combined abdominal-perineal resection with permanent colostomy is the only answer to lesions in the rectum and sigmoid, or whether we believe that in many cases an operation permitting conservation of the function of the anus is possible, we must agree with Dr. Mayo when he states "an open and thoughtful mind is essential to medical progress." We are too often prejudiced either by a few unfortunate experiences of our own or a few equally fortunate survivals. To that might be added another prejudice, to quote Dr. Mayo: "I also have observed that those who most criticize that type of operation have seen it done the least often."

I think that we will agree that for the first or lowest segment described by Dr. Mayo, abdominal-perineal resection with permanent colostomy is the operation of choice. I am inclined to believe that this operation is also the operation of choice for almost all of the lesions which fall in the next category, that from 6 to 11 cm. above the dentate margin. A good case is made out by the proponents of the pull-through operation and also the proponents of the low anterior resection. I have had no personal experience with the pull-through operation. So far as the anterior resection in this area is concerned, I do not feel that I can get sufficient segment on either side of the tumor to insure a reasonably radical procedure. Perhaps this is due to the unfortunate experience of seeing local recurrence on several occasions where it was thought that at the time of operation there was adequate bowel on either side of the tumor, and, so far as microscopic evidence could demonstrate, this was so. Unfortunately, even histologic examination of the cut end does not always guard against the existence of submural metastatic areas or invasive areas. For this reason, I am inclined to resect as much tissue as is in any way practical. For the third group I would still tend toward the combined abdominal-perineal resection unless the growth was easily mobilized together with a rather large cuff of apparently normal tissue on either side. This may place the line of anastomosis uncomfortably low in the pelvis. I have no quarrel with those who can perform a satisfactory anastomosis at this level, but I find it rather awkward. So far as the fourth group is concerned, I am inclined to agree with Dr. Mayo that many of these can be treated by segmental resection. Certainly the five-year survivals in the group so treated compare very favorably with those found after abdominal-perineal resection, and there is no question about the comfort of the patient or of the economic load of his hospitalization.

Dr. Mayo's statement that his patients are prepared physically and mentally for a combined abdominal-perineal resection is very important. This makes it possible for the surgeon to exercise a reasonable choice after the abdomen has been opened and the dissection begun and at the same time spares the patient the sudden realization that he has a permanent colostomy. In the final analysis, the general condition of the patient, the peculiarities of his own lesion, and the technical ability and open-mindedness of the operating surgeon will determine the proper operation for that patient.

RENAL LIPOMATOSIS

FRANKLIN C. FARROW, M.D., F.A.C.S., JAMES B. CROSS, M.D., F.A.C.S.,
SIEGFRIED TANNHAUSER, M.D., and JOSEPH T. ANDREWS, M.D.,* Buffalo, New York

(From the Departments of Urology and Pathology, Deaconess Hospital and the University of Buffalo School of Medicine)

RENAL lipomatosis, until recently regarded as a rare condition, is a relatively little known pathologic entity in which varying amounts of destroyed renal parenchyma become replaced by fat. Renal lipomatosis (fatty replacement of the kidney), lipomatous paranephritis (fatty transformation of the kidney), and lipomatous nephritis are a few of the other terms used to describe essentially the same condition. In the early literature renal lipomatosis was not clearly differentiated from true renal lipoma. The latter condition is one in which a circumscribed fat tumor occurs within a normal kidney parenchyma, usually at the periphery attached to the capsule, and is quite rare, the autopsy incidence being reported as one in 40,000.[1,2]

A number of investigators agree that renal lipomatosis can no longer be considered a rare process. This is very pointedly borne out by the easy discovery in 1938 by Roth and Davidson of 37 examples of this condition in an average museum of pathology designed for teaching purposes.[3]

Fatty replacement of the kidney was first reported by Baader in 1778.[4] Fifty-nine years later (1837), Rayer recorded the first detailed description of this process.[5]

It is generally agreed that renal lipomatosis is a condition which does not present a clinical picture all its own. In fact, it never has been diagnosed as such preoperatively or prior to necropsy. The symptoms which cause a patient having this abnormal process to seek treatment are usually those of pyonephrosis or pyelonephritis. These most commonly are pain over the kidney region and pyuria with dysuria. If the course has been of long standing, the kidney may have ceased to function with resulting minimal or absent symptomatology. The literature contains a number of examples of autopsy discovery of renal lipomatosis in persons meeting sudden death who had been perfectly well at the time of their passing.

Since renal lipomatosis is ordinarily a unilateral condition, blood chemistry and renal function tests are usually normal. Ureteral catheterization, however, often shows the involved kidney to be functionless. A very few cases of bilateral renal lipomatosis are on record.[6]

Fatty replacement of the kidney has been found most commonly in people of middle age. Extreme variations, however, have been reported, the youngest being a child of eleven and the oldest a man of seventy-seven.[7,2] Several authors have reported that, in their observations, renal lipomatosis was encountered only in obese patients.[8]

There are many theories which attempt to explain the etiology of renal lipomatosis. Borst feels that a proliferation of fatty tissue such as fills in the defect produced by muscular atrophy in certain types of dystrophy is active here too.[9] We are all cognizant of such other examples of replacement of an organ by fat, as the normal replacement of the thymus in children and the pathologic replacement in the myocardium of some middle-aged and elderly persons. Borst also points out the contention of Perls-Neelsen, Rokitansky, and others that the renal substance is destroyed by pressure atrophy as a result of fatty tissue proliferation. However, no evidence of compression of the renal parenchyma adjacent to the fatty tissue can be demonstrated to lend support to such a theory. If the process of the spreading fatty tissue were an invasive one passing across the boundary of the renal sinus, one would expect to find islets of renal tissue between the fat accumulations. Still other investigators have posed the theory that the adipose tissue arose by a process of metaplasia following proliferation of the kidney connective tissue. Most investigators, however, support the belief that fat from the renal sinus moves in to replace destroyed renal parenchyma.[2,10–14] Since the lining of the sinus is a prolongation of the kidney capsule, the fat therein is extrarenal and in direct continuity with the perirenal fat.

It is generally agreed that the destruction of the renal substance anteceding fat replacement is accomplished most frequently by longstanding infection. This is practically always nontuberculous, although tuberculosis has been reported as preceding or accompanying this condition.[8,15] Kutzmann tabulated 33 cases, and, of these, 79 per cent had renal calculi, and all showed evidence of infection.[14] It is probable that the infection is, in most cases, secondary to obstruction of the extrarenal urinary passages. Seven of Young's 11

cases showed replacement of a hydronephrotic kidney by fat.[16] One might expect such a substitution in a slowly progressing hydronephrosis where the increase of bacteria is encouraged and where a pyelonephritis or pyelonephrosis is an intermediate development. On the other hand, in the case of an acute hydronephrosis which has developed in a comparatively short period of time, one would not expect to find fatty replacement of the renal substance because infection had not had sufficient time to wreak destruction in the renal parenchyma.

Hamm and de Veer cite cases substantiating their contention that lipomatous tissue can replace renal parenchyma lost in noninflammatory conditions such as senile atrophy and the arteriosclerotic contracted kidney.[8]

Eight new cases of renal lipomatosis, some of which suggest a new mechanism for the development of this condition, are reported in the ensuing paragraphs. Seven of these cases were encountered in a series of 40 consecutive nephrectomies performed in a twenty-four-month period immediately preceding April, 1948. Renal lipomatosis was found once in the course of 308 consecutive necropsy examinations in the same period of time.

Case Reports

Case 1.—Mrs. E. F., age fifty-two, was admitted to the Deaconess Hospital March 26, 1946, with a history of recurrent attacks of severe left costovertebral angle pain, accompanied by chills, fever, and emesis for the past year.

Physical examination showed marked tenderness and spasm in the left costovertebral angle and left anterior abdomen.

Urinalysis showed pH 5.2 and albumin 2 plus; a microscopic specimen was loaded with pus and red blood cells. Blood count was as follows: 22,000 white blood cells with a left shift in the differential. The nonprotein nitrogen was 36 mg. per 100 cc. The carbon dioxide combining power was 39.4 volumes per cent. Cystoscopy revealed a chronic cystitis with drainage of purulent material from the left ureteral orifice which cultured as nonhemolytic Staphylococcus aureus. Urine from the right kidney was clear and negative on culture. Preoperative diagnosis was left pyonephrosis.

A left nephrectomy was performed on April 2, 1946. In the course of the operation a large perinephritic abscess was encountered and drained. The incision was closed with drainage. She had an uncomplicated convalescence.

The pathologic report was as follows: The kidney and attached tissue involved in the pathologic process weighed 700 Gm. The capsule was firmly fused to the kidney substance. The renal parenchyma

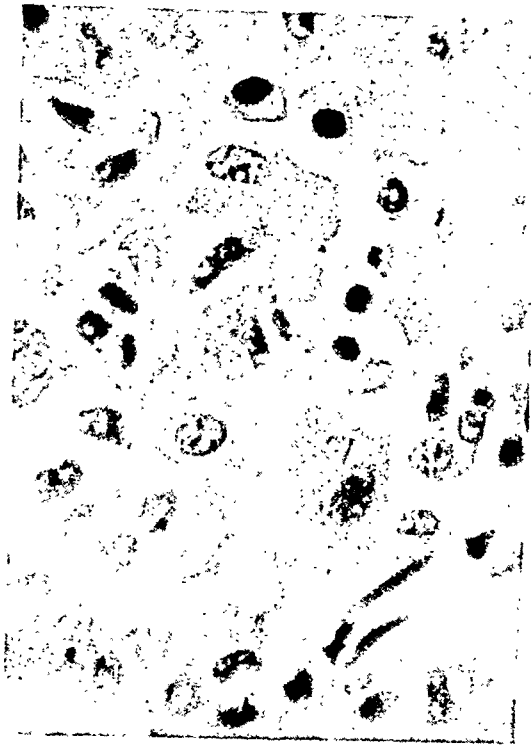

FIG. 3. Case 2: Granulomatous area, mainly plasma and round cells with various types of macrophages, some of them containing lipoid. (400 ×)

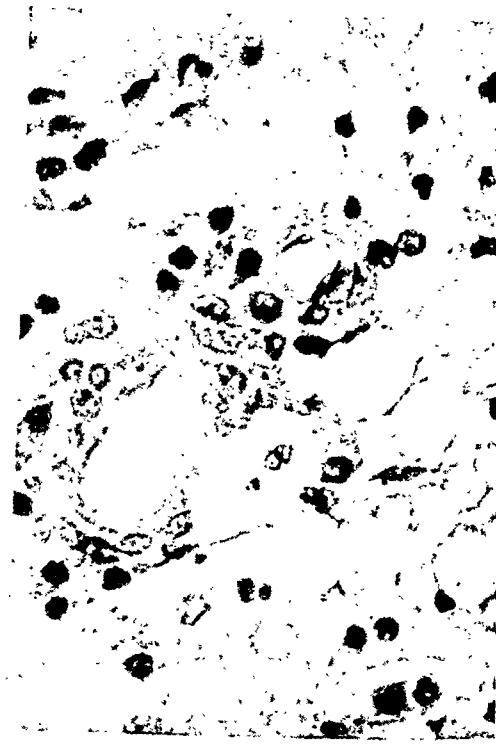

FIG. 4. Case 2: Mature fat cells scattered throughout lipoid granuloma deep in renal parenchyma. (400 ×)

showed a whitish, gelatinous, and fibrotic appearance on section in which no details of the normal gross kidney structure could be recognized. The calyces were greatly dilated and were surrounded by a rim of yellowish, necrotic-appearing tissue. They and the pelvis contained dark, grayish-red masses of shaggy matter floating in a thin purulent exudate. The fatty renal capsule appeared to be continuous with areas of fat in the kidney parenchyma, particularly in the hilar region. A perirenal abscess cavity was also noted.

In all the microscopic sections only small areas of recognizable kidney tissue were noted. Even in these areas the tubules had been obliterated by a proliferating fibrous tissue. Other areas consisted of a subacute granulation tissue in which round and polymorphonuclear cells predominated (Figs. 1, 2). Still other areas showed great masses of foam cells (lipoid macrophages) interspersed with round and polymorphonuclear cells. The separation between the granulation and necrotic tissue and the fat tissue was not sharp. Fat cells were noted singly, in small numbers, and also in large accumulations. In a few areas the foam cells and mature fat cells were mixed.

The final pathologic diagnosis was pyonephrosis with complete disintegration and fatty metamorphosis of the kidney tissue.

Case 2.—Mrs. A. S., a white woman, sixty-six years of age, entered the Deaconess Hospital on February 12, 1947, with complaints of dull, aching right-sided pain, loss of weight, and a gradually enlarging right abdominal mass.

Examination revealed her to be pale and poorly nourished, with a blood pressure of 160/90 and a palpable right-sided mass about 16 cm. in diameter.

Urinalysis showed albumin 3 plus and many pus cells on microscopic examination. Blood counts revealed marked anemia. Her white count and differential count were normal. The sedimentation rate was 17 mm. per hour. The nonprotein nitrogen was 26 mg. per cent. Other blood chemistry studies (chlorides, total serum protein, and albumin-globulin ratio) were normal. Examinations of urine for tumor cells on several occasions were negative. At cystoscopy a nonfunctioning right kidney was found, with obstruction in the ureter at 11 cm.

Pyelograms showed a normal left kidney. There was nonfilling on the right side above the level of the fourth lumbar vertebra. The right kidney was twice the normal size with a staghorn calculus present. Preoperative diagnosis was right calculus pyonephrosis.

After a series of blood transfusions and general supportive measures, the patient's red blood count increased to 4,060,000 cells.

A right nephrectomy was performed on February 26, 1947, under sodium pentothal anesthesia. Her postoperative course was uneventful, and she was discharged fifteen days after operation. Outpatient department records indicate that this patient gained 10 pounds in the first two months after operation and that her general health was much improved.

The pathologic report was as follows: The extirpated kidney weighed 500 Gm. Hemisection of the organ revealed a striking picture of a fatty, fibrous, nodular tissue replacing the normal architecture. The pelvis was distended by purulent matter; two portions of a staghorn calculus were contained in this thick, heavy, purulent exudate.

Microscopic examination showed the kidney parenchyma to be almost completely replaced by fat and a granulation tissue presenting evidence of a subacute inflammation (Fig. 3). This replacement tissue had infiltrated between remnants of the tubules and glomeruli. The inflammatory cells included segmented granulocytes, plasma cells, round cells, and fibroblasts of varying ages. Extensive areas, composed of lipoid macrophages (typical foam cells), were noted scattered throughout the granulation tissue. In some of these macrophages the transition to typical fat cells can be traced. The majority of these cells showed the usual dense foamy cytoplasmic pattern with central location of the nucleus. In certain of these cells, however, the foamy pattern showed clearing, and moving of the nucleus to the cellular border (Fig. 4). No reticular framework was left in certain of these cells, thus making them indistinguishable from adult fat cells. They were often seen to be still surrounded by the cells comprising the lipoid granuloma. The scanty remnants of kidney parenchyma showed various degrees of degeneration such as intercapillary sclerosis of glomeruli, thickening of the capsule of Bowman, and hyalinization of whole glomeruli.

The final pathologic diagnosis was fatty replacement of kidney tissue in pyonephrosis.

Case 3.—Mrs. M. S., age thirty-eight, was admitted to the Deaconess Hospital on January 12, 1947. She complained of right upper quadrant pain and tenderness with recurrent attacks of chills and fever, a weight loss of 30 pounds in four months, frequency, dysuria, and occasional nocturia.

Examination revealed an obese white woman with a poorly defined mass in her right upper quadrant. Laboratory findings were essentially negative.

At cystoscopy an obstructing calculus 1 cm. in diameter was found. The right kidney pelvis and calyces were markedly dilated above this and had a serrated, "moth-eaten" appearance on x-ray examination, with no function from this side. The psoas muscle shadow was obliterated on the right. The left kidney was normal. Preoperative diagnosis was right perinephritic abscess with right pyonephrosis.

At operation on January 27, 1947, a perinephritic abscess was encountered and drained. Approximately 300 cc. of purulent matter was evacuated. Cultures on this pus showed a heavy growth of Bacterium coli. The patient was discharged on February 6, 1947, still having a small amount of serous drainage from her incision.

On April 12, 1947, this patient was readmitted for nephrectomy. Since her last discharge she had felt well and had been able to do her housework every day. She had had sporadic purulent drainage from the operative incision in her right flank. Slight right costovertebral angle pain was experienced when drainage was minimal or had stopped; this subsided when drainage again commenced. She had noticed moderate dysuria and nocturia once nightly during the week preceding admission.

A right intracapsular nephrectomy was performed on April 14, 1947, without incident. Her postoperative course was uneventful. She was discharged on April 29, 1947.

The pathologic report was as follows: The removed kidney weighed 110 Gm. Cross section showed the normal kidney architecture to be destroyed and replaced by areas of softening and necrosis in the region of the cortex and medulla. These areas which were scattered throughout the kidney substance were 1 to 2 cm. in diameter. The normal structure of the pyramids was replaced by yellowish-gray fibrous tissue.

Microscopically, the normal renal structure was seen to be completely destroyed, except for occasional tubular structures and glomerular remnants. There were large necrotic-appearing areas in which polymorphonuclear cells, round cells, and predominantly huge lipoid macrophages were the principal constituents. Large areas of hemorrhage and the occasional presence of true lymphoid follicles with germinal centers were also noted. There was no evidence of tuberculosis. In some of the necrotic-appearing regions the lipoid macrophages were seen to be apparently moving into the accumulations of round cells, plasma cells, and polymorphonuclear leukocytic debris. Some of these macrophages showed clearing of their reticular structure and marginal location of their nuclei. In other areas the fat cells were present in chronic granulation and markedly fibrotic tissue, similar to the fat metamorphosis sometimes found in the submucosa of the appendix following inflammation.

The final pathologic diagnosis was chronic pyelonephritis and pyonephrosis with beginning metaplasia of the kidney tissue.

Case 4.—Mrs. A. G., a forty-five-year-old housewife, was admitted to the Deaconess Hospital on March 7, 1947, stating that she had had an attack of intense right upper quadrant abdominal pain, lasting for seven days, two months prior to admission. Subsequent x-ray studies revealed what seemed to be a kidney stone.

A right upper quadrant mass, the size of a large grapefruit, was felt on physical examination. This was separate from the liver and was slightly tender. Some right costovertebral angle tenderness was likewise noted.

Cystoscopic examination revealed a nonfunctioning right kidney with no dye excretion in fifteen minutes. The left kidney was normal.

Roentgenologic studies showed a staghorn calculus in the vicinity of the right kidney; several small calculi were seen lying just inferior to the larger one. Intravenous urography indicated a normal pelvis, calyces, and ureter on the left side. There was no

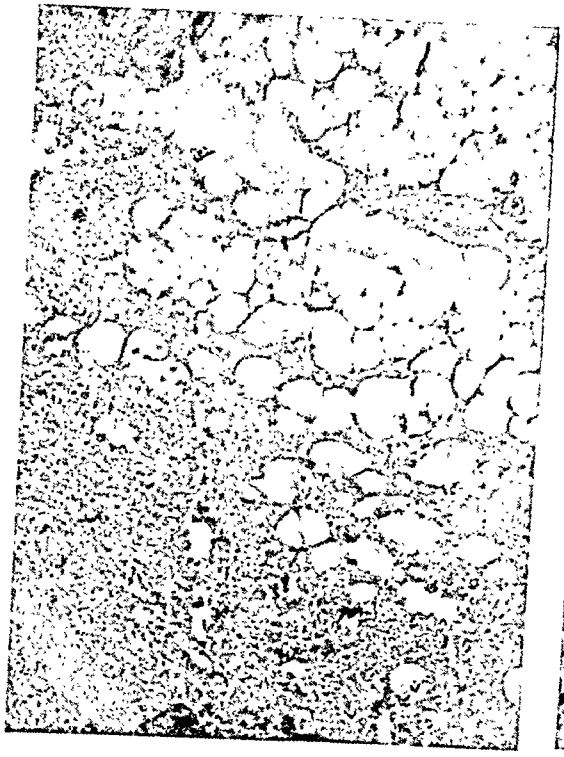

FIG. 5. Case 4: Chronic inflammatory tissue, mature fat tissue, and lipoid granuloma. No sharply demarcated boundaries are demonstrable between the renal tissue and the lipoid granuloma. (100 ×)

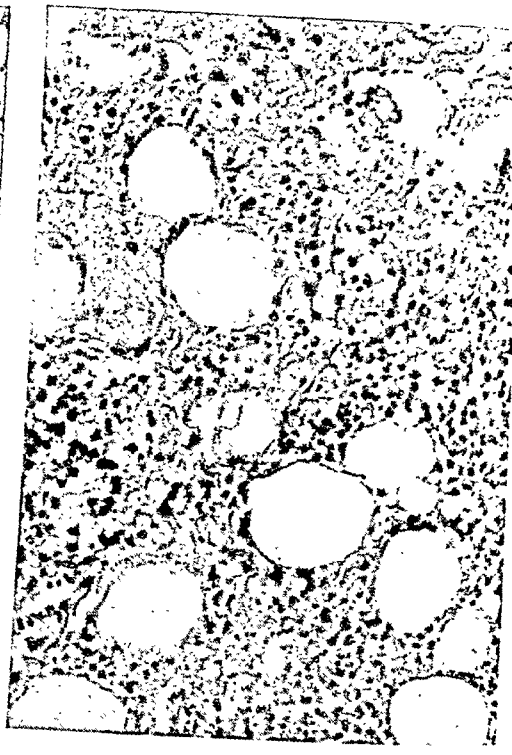

FIG. 6. Same as Fig. 5. (200 ×)

excretion of the injected dye on the right in thirty minutes. Preoperative diagnosis was right calculus pyonephrosis.

A right intracapsular nephrectomy was performed on March 17, 1947. This type of procedure was deemed advisable because the kidney was small and surrounded by approximately 3 cm. of dense, scarred fatty tissue. The incision was closed with drainage. The patient's postoperative course was uneventful.

The pathologic report was as follows: The extirpated kidney weighed 130 Gm. and measured 9 by 5 by 5 cm. in size. Upon section, this organ was seen to be almost entirely composed of fat. Only at its lower pole was there a small amount of tissue having any semblance of renal parenchyma; this appeared to be markedly inflamed. A large staghorn calculus was found embedded in the shaggy inflammatory tissue.

Microscopic study of representative portions of this specimen revealed necrotic masses, surrounded by a chronic granulation tissue, partly enclosed in a fibrous capsule (Figs. 5, 6). Although this necrosis appeared somewhat caseous, nothing in the immediate vicinity indicated a tuberculous process. This diagnosis, however, could not be excluded on the basis of these microscopic sections. Mature fat tissue was observed interspersed with chronic granulation tissue, round cell accumulations, and fibrotic tissue.

The final pathologic diagnosis was marked fatty replacement of the kidney.

Case 5.—Mrs. H. K., a thirty-six-year-old housewife, was admitted to the Deaconess Hospital on September 12, 1947. She complained of attacks of sudden severe right upper quadrant abdominal pain, extending through to the region of the right costovertebral angle, of six months duration. These attacks were associated with fever, excessive perspiration, nausea, and emesis. In addition to the above symptoms, she also complained of nocturia (2 to 3 times), urgency, frequency of urination (20 to 30 times), and pyuria.

Physical examination on admission to the hospital revealed an obese woman having a tender, respiratory-mobile mass in the right upper quadrant of the abdomen extending four finger breadths below the costal margin.

X-ray examination of the abdomen on September 14, 1947, showed a large right kidney in an abnormally low position. A laminated shadow, having the appearance of a gallstone, was noted just to the right of the third lumbar vertebra. On September 17, 1947, intravenous urograms showed excretion of the dye in good concentration on the left in five minutes. No excretion of the dye was noted on the right by x-ray in eight hours.

Cystoscopic examination was carried out on Sep-

tember 19, 1947. No phenolsulfonphthalein returned from the right ureteral orifice; the dye appeared from the left ureteral orifice, in normal concentration, in four minutes. Retrograde pyelograms showed that the calculus, seen on x-ray films taken five days previously, was in the right renal pelvis. A suggestion of a filling defect in the pelvis about the calculus was noted. The dye did not fill the calyces of this kidney. Preoperative diagnosis was right calculus pyonephrosis.

On September 22, 1947, the right kidney was removed.

The pathologic report was as follows: This organ weighed 200 Gm. and measured 13 by 7 by 6 cm. in size. The capsule stripped with difficulty; in some areas it was so adherent that the stripping was almost impossible. On hemisection a greatly dilated pelvis and calyces having a ragged hemorrhagic lining were noted. The renal parenchyma was white and fibrous in appearance and showed focal, yellowish, fatty nodules adjacent to the calyces. Most of the characteristic kidney structure could no longer be identified.

Microscopic examination showed far-advanced destruction of the kidney parenchyma and especially of the convoluted tubules. Massive interstitial infiltration of round cells, plasma cells, and polymorphonuclear leukocytes was strikingly evident. The glomeruli appeared to be somewhat better preserved; their capsules, however, were thickened and in some areas showed various degrees of degeneration. The wall of the kidney pelvis showed marked infiltration by polymorphonuclear leukocytes and round cells. Free pus was noted in the lumen of the pelvis. Certain areas presented a picture of marked interstitial fibrosis which had advanced to such a degree as to make the kidney tissue all but unidentifiable. Fat was seen to be invading the renal substance in these areas. The transition from a chronic granulomatous tissue to one made up chiefly of fat-containing macrophages to true fatty tissue was clearly observed.

The final pathologic diagnosis was chronic calculus pyelonephritis and pyonephrosis with beginning fatty metaplasia.

Case 6.—Mrs. M. L., a forty-year-old housewife, was admitted to the Deaconess Hospital on November 9, 1947, complaining of pain in the right costovertebral angle, urgency, frequency, nocturia, nausea, emesis, chills, and fever. These symptoms had persisted for four days prior to hospitalization. Her past history revealed that she had been treated for pyelitis and cystitis nine years before.

At the time of her admission this patient was noted to be well nourished. She had, however, a low-grade fever. Her blood pressure was 96/60. The remainder of the examination was negative except for marked tenderness and spasm noted in the right costovertebral angle extending down into the right lower quadrant of the abdomen. No masses were palpable.

A 3 plus albuminuria and many clumped white blood cells per high power field in the urine sediment were the only positive urinary findings. Blood studies revealed 4,620,000 red blood cells per cu. mm., 13.6 Gm. of hemoglobin per 100 cc. (Sahli), and 12,000 white blood cells per cu. mm. The differential count indicated a moderate shift to the left.

Cystoscopy revealed an infected bladder. An infected right hydronephrosis of 175 cc. capacity was found. Drainage from the left kidney was normal with clear urine. Phenolsulfonphthalein appeared in normal concentration from the left ureter in five minutes; none appeared on the right. Analysis of the urine from the right kidney revealed a 4 plus albumin and many white blood cells. The urine from the left kidney was negative. Retrograde pyelograms demonstrated the right ureter, pelvis, and calyces to be markedly distended, irregular, and ragged in outline. The left pyelogram appeared to be normal. Preoperative diagnosis was right pyonephrosis.

A right nephrectomy was performed on November 17, 1947, without incident. The organ was densely adherent to the peritoneum and was freed from this and the perirenal fat with some difficulty. The patient ran an essentially uneventful postoperative course and was discharged on her thirteenth postoperative day.

The pathologic report was as follows: The removed kidney weighed 240 Gm. and measured 12 by 7 by 6 cm. in size. The external surface was smooth. Hemisection showed the cortex to be atrophic and almost absent. The medulla was replaced by fatty tissue. The pelvis was markedly dilated.

Microscopic examination revealed evidence of chronic nonspecific pyelonephritis and pyonephrosis with extensive destruction of the kidney parenchyma. Accumulations of fat cells were seen in a matrix of hyaline fibrous tissue. A few lipoid macrophages were noted in the vicinity of the mature fat cells.

The final pathologic diagnosis was advanced fatty metamorphosis of the kidney tissue.

Case 7.—Mr. W. S., a fifty-four-year-old foreman, was admitted to the Deaconess Hospital on August 2, 1946, with the complaints of chills, fever, pyuria, and dull aching pain in the right flank for five days. He claimed to have had similar episodes every six to eight months for the past two years. About fifteen years previously he had passed several stones from his bladder.

Physical examination revealed a well-nourished man with tenderness and spasm over the right flank.

Blood studies were normal throughout. Urinalysis showed albumin 2 plus with many pus and blood cells microscopically.

Cystoscopy with pyelography showed a calculus pyonephrosis on the right side, with nonvisualization of the right psoas muscle and a small nonobstructing left ureteral calculus. The left ureteral calculus was removed several days later with a nylon loop and measured 14 by 6 mm.

One week later, August 28, the right kidney was explored and a large perinephritic abscess was drained. It was not feasible to remove the kidney at this time. He was discharged with a draining sinus from his right flank incision.

Sixteen months later he was readmitted to the hospital. He had gained 20 pounds in weight, and

his only complaint was the draining sinus in his operative scar.

Physical examination revealed an obese white man with a blood pressure of 130/90 and a sinus 5 mm. in diameter at the inferior border of his right flank incision.

Urinalysis again revealed albumin 2 plus with microscopic clumped pus. Blood studies were normal. Skiodan acacia, injected in the sinus tract, showed it to pass into the right kidney, filling the calyces, which were blunted and distorted. Intravenous pyelograms revealed a normal left kidney with a nonfunctioning right calculus pyonephrosis. Preoperative diagnosis was right calculus pyonephrosis.

At operation a sinus tract was dissected out to the region of the right kidney. It was surrounded by dense, fatty, and inflammatory tissue. An intracapsular nephrectomy was attempted, but because the kidney was very firmly adherent to the true capsule, this had to be abandoned. The kidney and surrounding mass of fatty, inflammatory tissue were removed by block dissection after the ureter had been identified and cut. The pedicle was tied off, but because of the shortness of the stump, one clamp was left in place on the pedicle. The incision was closed in layers with drainage. The clamp on the pedicle stump was removed in seventy-two hours.

The pathologic report was as follows: The specimen consisted of a lump of fat tissue roughly assuming the shape of a kidney. Hemisection showed that the renal parenchyma was almost replaced by fat and soft, fibrous tissue. Only at the lower pole an approximately cherry-sized piece of solid tissue, resembling that of kidney, was seen. Several calculi of varying size and shape were scattered throughout the specimen.

Microscopically, a small piece of fairly well-preserved kidney tissue was seen. This showed focal interstitial round cell and fibrous tissue accumulations as well as epithelial degeneration in the tubules. All glomeruli exhibited hyaline thickening of their capsules and basal membranes. The transition from the relatively well-preserved renal tissue to the adjacent fat tissue containing a few areas of fibrosis and some fibrotic remnants was abrupt.

The pathologic diagnosis was renal lipomatosis (fatty replacement of the kidney parenchyma) secondary to chronic purulent infection.

Case 8.—Mr. C. P., age eighty-one, expired twenty-one hours after admission to the Hospital. His death was attributed to a peritonitis secondary to a traumatic perforation of the rectum. An incidental finding at autopsy was a lipomatosis of the right kidney.

Gross examination of this organ showed marked thinning of the cortex and considerable fatty proliferation in the medulla. Extensive areas of interstitial, round, and plasma cell infiltration and fatty replacement in areas of destroyed parenchyma were noted microscopically.

Comment

Since renal lipomatosis appears to be a replacement process, one would expect to find it existing in varying degrees of progression. This was th case, not only in the eight patients herein r ported, but also in those reported in recent yea by other authors. In this series, five cases showe far-advanced replacement of the renal substan (Cases 1, 2, 4, 6, and 7). The process w moderately advanced in one (Case 8) an minimally present in two (Cases 3 and 5). might be expected, the earliest cases reported the literature where those of marked fatty r placement, for these first caught the attention the pathologist and surgeon. The case which w incidentally discovered at autopsy (Case 8) h developed without symptoms referable to t genitourinary tract.

Certain of these cases suggest a mechanism f the development of renal lipomatosis somewh different from those propounded by other i vestigators. These cases (Numbers 1 to 6) ind cate that the first stage of fatty replacement co sists in the formation of a lipoid granuloma. T macrophages of the granulomatous areas inge fat from the cellular debris of the destroyed kidn parenchyma and the abundant pus cells usual found in their neighborhood. It appears th then only, after this intermediate stage of lipo granulomatosis, the definite replacement by adu fat tissue takes place. Because of these findin it is not necessary to surmise that fat from t renal sinus moves in to fill the area destroyed infection. Fatty replacement is also seen in oth organs. For instance, the very common replac ment of the submucosa of the appendix followi chronic infection is well known. In this exampl invasion from a contiguous structure is not po sible.

Another finding which is somewhat differe from the pathologic picture described by ma investigators is that the demarcation of the fat tissue from the diseased kidney tissue, althou structurally still identifiable, is not sharp. definite capsule separating these two types tissue was not seen in this series of cases. Acc mulations of fat cells were found far inside t granulomatous area; these were never found noninfected kidney tissue.

A number of investigators have reported th general obesity is a usual finding in cases of ren lipomatosis. This is not substantiated in th series of cases, for half of the eight cases were average or slight physique.

The equal distribution of renal lipomatosis, regard to side involved and sex as reported b numerous authors, was likewise not found in th series of cases. All except two (Cases 7 and were found in women, and in seven of the eig cases the right kidney was involved in th pathologic process.

In certain investigations the idea was brough

rward that the most advanced type of renal pomatosis occurs after drainage of an advanced lculus pyonephrosis and that the many reported ses, having either a spontaneous or postopera-ve draining sinus, substantiate this view. Two f this series of eight cases had draining sinuses rior to nephrectomy. One of these (Case 7) had ad surgical drainage of a kidney abscess contain-g calculi with a subsequent persistent draining nus sixteen months prior to removal of his idney. Pathologically this specimen presented picture of advanced renal lipomatosis. The ther case (Case 3) had had a kidney abscess rained three months prior to nephrectomy. A raining sinus had persisted in the interval be-veen operations. In this latter instance the idney was pathologically diagnosed as a chronic yelonephritis and pyonephrosis with beginning pomatous metaplasia of the kidney tissue.

Thus we have two cases exhibiting persistent raining flank sinuses between surgical drainage f kidney abscesses and nephrectomy. The xtirpated kidney in one showed very early fatty ansformation, whereas the other presented a icture of far-advanced renal lipomatosis. These xtreme pathologic variations of fatty replace-ent in cases of draining flank sinus would sug-est that the persistence of a sinus per se is due ntirely to blockage of the extrarenal urinary pas-age and that it is not necessarily an accompani-ent of renal lipomatosis. The development of enal lipomatosis is favored in complete blockage ecause the resulting stagnation of urine is con-ucive to bacterial increase which, in turn, favors nfection of the renal substance. The cases herein eported all showed evidence of severe infection f the parenchymal kidney tissue. The case emonstrating minimal fatty change with a drain-ng flank sinus was found in a thirty-eight-year-ld individual who was unequivocally shown to ave a complete blockage at the ureteropelvic unction.

It is reasonable to postulate that cases having alculi in the pelvis or calyces can readily have the elvic outlet occluded by one, or a part of one, of hese calculi. With the development of increased ressure behind such a stone and formation of edema in the ureteropelvic tissue adjacent there-o, the obstruction can become complete. Follow-ng release of a resulting increased intrapelvic pres-ure by surgical incision of a pyonephrosis or erirenal abscess communicating with the pelvis, an adequate exit for the contained urine and pus is established. In time the edema about the im-pacted ureteropelvic calculus has a chance to sub-side, and unless the stone has eroded into and be-come attached to the wall of the pelvis or ureter, a partial ureteral passage may again be established. However, if the obstruction at the pelvic outlet is not relieved, either by surgical intervention or by a subsiding of the edema about a stone, a persistent sinus very likely will result if there is any function of the particular kidney in question.

A careful search for calculi in the pelvis and calyces is indicated when a distended kidney pelvis is opened into for any cause. If all stones are removed, the possibility of their occluding the normal urinary passages, and so encouraging a persistent flank sinus, is obviated. The taking of portable x-ray films of the kidney area on the operating table can be a valuable aid in the location of such stones. Using a technic advocated by Sosman, a developed and fixed film of the kidney in question can be viewed by the operating surgeon ten minutes after its exposure.[17] Since 80 per cent of renal stones contain enough calcium to be seen on roentgen examination, the use of contrasting radiopaque dye has not been considered necessary.[18] In the case of stones associated with intrapelvic infection, the percentage of calculi containing enough calcium to be detectable by roentgen examination probably approaches 100 per cent.

Five of the seven cases which were operated upon showed no phenolsulfonphthalein excretion from the side involved by the fatty replacement. Another (Case 7) showed a poor concentration of the dye from the affected kidney eight minutes after it was injected intravenously. Ureteral catheterization was not attempted in the other case (Case 1) because of the patient's poor reaction to cystoscopy. The passage of thick pus from the left ureteral orifice, however, was noted prior to removal of the cystoscope.

The removal of kidneys in which fatty replacement has progressed to an advanced degree is often technically difficult. The adipose tissue usually found in renal lipomatosis is much firmer than ordinary fat. If too much of this is caught between clamps being closed across pedicle vessels, proper occlusion of the latter cannot be accomplished. The toughness of the fat found in renal lipomatosis can be understood when one observes the fibroblastic proliferation and round cell infiltration in microscopic sections. Because of the unyielding firmness of this tissue, intracapsular nephrectomy was the operative procedure in three of the seven cases taken to surgery.

Summary and Conclusions

1. Eight new cases of renal lipomatosis are reported.

2. Microscopic analysis suggests a new theory regarding the pathogenesis of this condition, namely, that lipomatosis develops through the transitional stage of a lipoid granuloma which is then replaced by adult fat tissue. It is felt that no invasion from the renal sinus is necessary to ex-

plain this replacement. Attention is drawn to similar processes in the chronic inflammation of other organs.

3. The role of renal calculi in establishing and maintaining severe renal infections is stressed.

The x-ray findings were reported by Dr. Roy E. Seibel, roentgenologist, Deaconess Hospital.

Discussion

Albert M. Crance, M.D., *Geneva.*—Drs. Farrow, Cross, Tannhauser, and Andrews are each to be congratulated on the excellent preparation of this treatise on renal lipomatosis, so ably presented by Dr. Farrow. It is an excellent piece of pathologic research. Unquestionably, there is such a thing as fat replacement in a kidney damaged by some other cause, and in rarer instances, as they have mentioned, it appears to exist in otherwise normal kidneys. The fact that pathologists have encountered it at autopsy in cases of sudden death, in which no urologic symptoms appeared to have existed is proof of this.

However, in seven of the eight cases they are reporting, the kidney was removed, not because of lipomatosis, but for obvious reasons of pyonephrosis, hydronephrosis, and calculi, including staghorn calculi, in a nonfunctioning kidney. In other words, after the kidney was removed, they were able then, and only then, to add this pathologic entity to their diagnoses.

The writers have very clearly stated that fat replacement is apparently concomitant with other pathology and that it is not a condition we are going to be able to diagnose preoperatively. Therefore, we should not be too concerned about its presence clinically. It certainly would not appear to be a condition which will affect us, as urologists, in our judgment concerning the management of renal disease. It is, moreover, a pathologic entity occurring *with* or more often *following* other pathology.

Some twenty years ago I removed a left kidney from a man fifty-two years of age—a nonfunctioning, grossly bleeding kidney with elongated and narrowed calyces, typical of renal neoplasm. Upon exposing the kidney, there was no external evidence of tumor except that the kidney felt very hard and its cortex was studded with peculiar, deep yellowish deposits. On hemisection, it was like cutting through a large lipoma, no normal kidney tissue remained. The pathologist termed it fatty degeneration of the kidney. I really feared at the time that this patient would in all probability develop a similar condition in the opposite kidney, although a normal preoperative pyelogram and normal function existed on the right side. However, he is now in his seventies, very much alive and well. I wonder now if this was possibly not an extreme case of the very condition Dr. Farrow has presented to us today.

One thing is certain—we will probably have a keener interest in the pathology of those kidneys which, in the future, we will find reason to remove. On the other hand, we will not be performing nephrectomies because of the diagnosis of lipomatosis but rather for a major condition which has damaged the kidney sufficiently to cause this destroyed tissue to have been replaced by fat.

SMEAR TEST DETECTS INACCESSIBLE CANCERS

Earlier detection of cancers arising in the gallbladder, pancreas, and certain bile ducts appears to be possible by use of the smear test, two Boston doctors reported in the September 24 issue of the *Journal of the American Medical Association.*

The test is the most hopeful technic yet described for early detection of this group of otherwise obscure and inaccessible malignant tumors which accounts for at least 10,000 deaths annually in the United States, say Drs. H. M. Lemon and W. W. Byrnes.

The smear test is based on examination under the microscope of shed body cells to see if cells indicating a malignant condition are present. Sediments of material taken from the portion of the small intestine adjoining the stomach are stained by the method developed by Papanicolaou.

The doctors studied 38 patients with nonmalignant disease of the liver, pancreas, small intestine, and biliary tract and 16 patients with proved cancer of these areas.

In none of the patients with nonmalignant disease did the smear test show even questionable evidence of cancer. In the 16 cases of proved cancer, 11 were suspected or diagnosed from the smear test.

JRETEROSIGMOID ANASTOMOSIS BY DIRECT ELLIPTIC CONNECTION

EED M. NESBIT, M.D., and A. WAITE BOHNE, M.D., Ann Arbor, Michigan

THE need for improvements in the technic of ureterointestinal anastomosis has long been preciated by surgeons familiar with this opera- n. To date, some fifty to sixty different meth- have been conceived or tried. The operation cribed in the present communication employs ct anastomosis of the ureter to the bowel. oes not involve a new surgical procedure, for is one of 11 surgical plans or principles which been applied to the implantation operation. ne plan of direct anastomosis was probably performed on a human being in 1878 by h. His procedure consisted chiefly of an o-side anastomosis, suturing mucosa of r to mucosa of bowel. This was a tedious ainstaking process; leakage was common- and the results not spectacular. A similar ic of direct anastomosis was described in by Reuben Peterson who, instead of an -side connection, followed the principle n small bowel surgery and made a side-to- ion. This was only in dogs and, as far as vn, was never performed on humans.

her of the above two plans gained very ceptance. Even at that time, most sur- elt that it was essential to provide some a valvelike mechanism at the anastomotic order to prevent direct reflux of fecal l into the urinary tract and at the same cure maximum protection against the sent danger of leakage. The tunneling n, popularized by Coffey, in which the as buried in the bowel wall, fulfilled these uirements and became, therefore, the n of choice.

nnel principle, however, was not without , since it was readily observed that any ng dilatation of the ureter, other than precluded the use of this method. Like- greatest cause for failure after implan- s stricture formation at the anastomotic resultant hydronephrotic dilatation of tract and subsequent renal insufficiency. ture formation occurred at one or more laces in the anastomosis—at the pro- eteral stump, in the tunnel area itself, erosal margin where the ureter entered (Fig. 1).

th the advent of sulfa drugs and anti- biotics, complete cystectomy for carcinoma of the bladder was not always performed when it might seem indicated, because pre-existing dilatation of the ureters or the ever-present fear of stricture formation often led the surgeon to choose a less radical procedure not necessitating ureterointestinal transplantation.

The operation presented here again reverts to the principle of direct anastomosis and eliminates entirely the tunnel procedure with its inherent faults (Fig. 2). Instead of a direct connection by Smith's end-to-side technic or a side-to-side

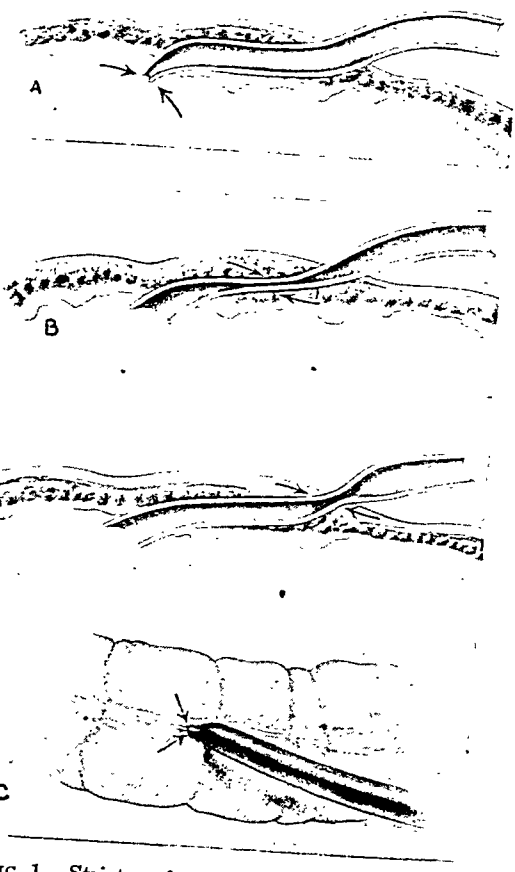

FIG. 1. Stricture formation in the anastomosis: (A) at the projecting ureteral stump, (B) in the tunnel area itself, and (C) at the serosal margin where the ureter entered the bowel.

by invitation, at the 143rd Annual Meeting of ociety of the State of New York, Buffalo, Sec- gy, May 5, 1949.

plain this replacement. Attention is drawn to similar processes in the chronic inflammation of other organs.

3. The role of renal calculi in establishing and maintaining severe renal infections is stressed.

The x-ray findings were reported by Dr. Roy E. Seibel, roentgenologist, Deaconess Hospital.

One thing is certain—we will probably have a keener interest in the pathology of those kidneys which, in the future, we will find reason to remove. On the other hand, we will not be performing nephrectomies because of the diagnosis of lipomatosis but rather for a major condition which has damaged the kidney sufficiently to cause this destroyed tissue to have been replaced by fat.

SMEAR TEST DETECTS INACCESSIBLE CANCERS

Earlier detection of cancers arising in the gallbladder, pancreas, and certain bile ducts appears to be possible by use of the smear test, two Boston doctors reported in the September 24 issue of the *Journal of the American Medical Association.*

The test is the most hopeful technic yet described for early detection of this group of otherwise obscure and inaccessible malignant tumors which accounts for at least 10,000 deaths annually in the United States, say Drs. H. M. Lemon and W. W. Byrnes.

The smear test is based on examination under the microscope of shed body cells to see if cells indicating a malignant condition are present. Sediments of material taken from the portion of the small intestine adjoining the stomach are stained by the method developed by Papanicolaou.

The doctors studied 38 patients with nonmalignant disease of the liver, pancreas, small intestine, and biliary tract and 16 patients with proved cancer of these areas.

In none of the patients with nonmalignant disease did the smear test show even questionable evidence of cancer. In the 16 cases of proved cancer, 11 were suspected or diagnosed from the smear test.

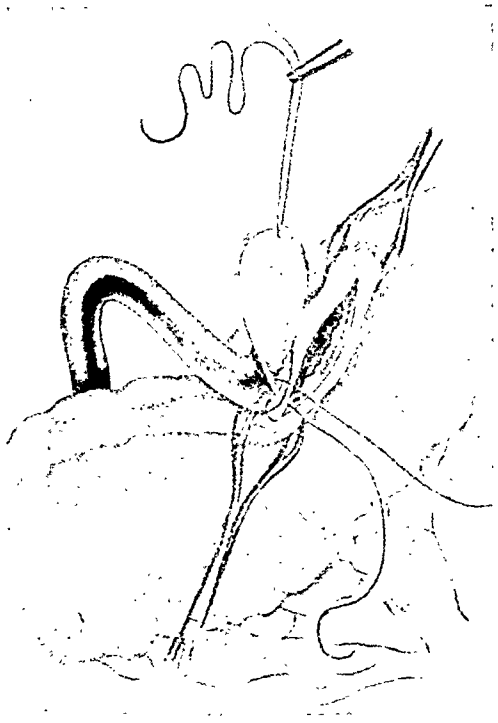

FIG. 5. Anastomosis readily accomplished, contiguous surfaces being of identical shape.

anterior superior spines, extending to the lateral border of each rectus muscle. Both rectus muscles are transected and the peritoneum opened. After packing off the small bowel, the ureter is identified just below the pelvic brim, the peritoneum overlying it incised, and the ureter picked up in a Babcock forceps. The ureter is then incised longitudinally on its posterior medial surface for a distance of approximately 1 to 1.5 cm. An appropriate portion of the sigmoid is then picked up between Babcock forceps and

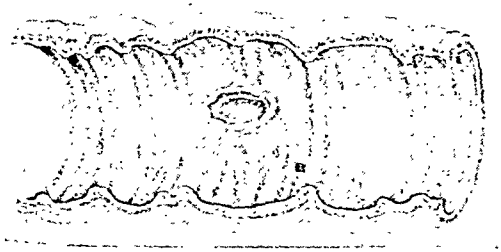

FIG. 6. Diameter of ureter not impinged on by constriction of connecting stoma.

accurate estimation of the exact implant site determined by coapting the ureter, sigmoid, and the parietal peritoneum in such a position that all structures will lie in the pelvis with no constriction or acute angulation when final fixation is performed.

The bowel is next incised longitudinally along the lateral taenia for a distance of 1 to 1.5 cm. Anchor or approximating sutures are then placed. The first of these sutures passes through all layers of the ureteral wall at the proximal end of the ureteral incision and then through all layers of the bowel at the superior margin of that incision. The second anchor stitch joins the distal portion of the ureteral flange to the inferior end of the bowel incision (Fig. 7). When slight traction is applied to these sutures, the edges of the bowel and ureter are brought into close apposition, facilitating the accurate placing of sutures. A grooved director inserted in the ureteral canal often aids in the accurate placing of sutures adjacent to the proximal anchor stitch. Anastomosis is then completed using 5 zero chromic catgut, either by interrupted technic or a running suture (Fig. 8).

Finally, the anastomotic site is anchored firmly to the lateral pelvic peritoneum in such a way as to preclude angulation or traction upon the

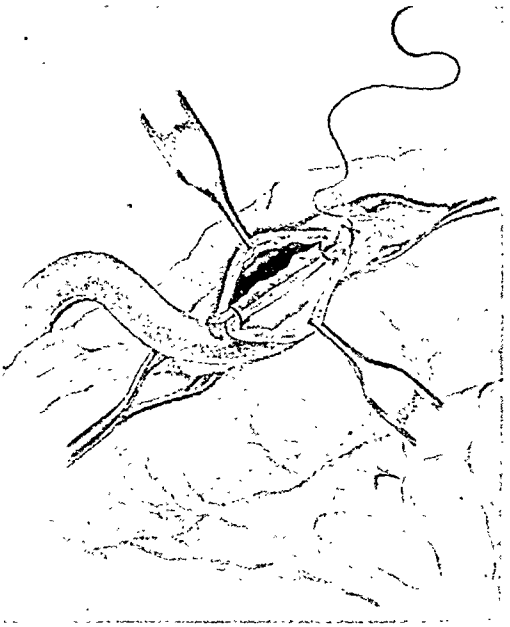

FIG. 7. Distal portion of ureteral flange is joined to inferior end of bowel incision by second anchor stitch.

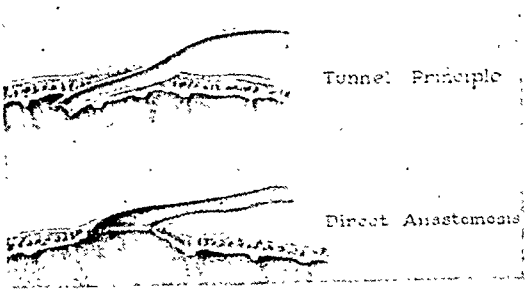

FIG. 2. Comparison of principles—tunnel procedure and direct anastomosis.

anastomosis, such as was used by Peterson, an oblique elliptic connection of ureter to bowel is performed. The free end of the ureter is incised longitudinally on one side, thus allowing the terminal portion of the ureter to assume a spoon-like shape (Fig. 3). The bowel is likewise incised longitudinally, which opening naturally becomes elliptic (Fig. 4). Anastomosis is now readily accomplished since the contiguous surfaces are of identical shape (Fig. 5). The advantage of forming a spatulate end of the ureter is to be found in the fact that this arrangement provides for an attachment to the bowel having a stoma with maximum diameter. Furthermore, any constriction of the connecting stoma will not impinge on the diameter of the ureter (Fig. 6). A simple running suture or interrupted sutures may be used, but all layers of each structure should be included, since only one layer of sutures is employed.

After completion of the anastomosis, it is extremely important that the bowel then be securely anchored to the parietal peritoneum in a position which will avoid angulation of the ureter.

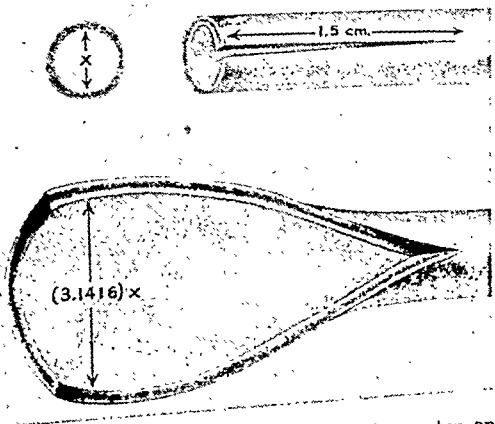

FIG. 3. Longitudinal incision of the ureter on one side allows the terminal portion of the ureter to assume a spoonlike shape.

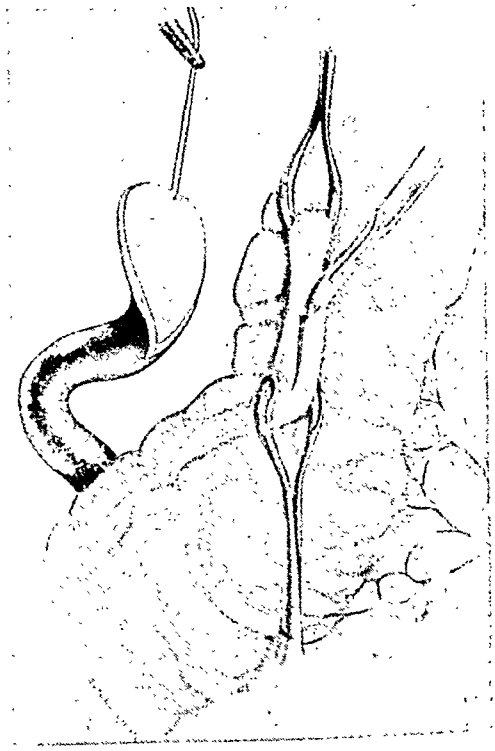

FIG. 4. Similar longitudinal incision of bowel which produces elliptic opening.

Operative Technic

The details of the technic are as follows: Laboratory studies of the nonprotein nitrogen, carbon dioxide combining power, hemoglobin, and white blood count are made. Intravenous pyelograms and x-ray of the chest are also obtained at this time. A three-day preoperative preparation consists of the following:

1. A modified Miles regime—1 ounce of a mixture of 1/4 ounce of magnesium sulfate crystals dissolved in 8 ounces of water given hourly, beginning at 6:00 A.M. and followed at 4:00 P.M. by a plain water enema. This is repeated daily.
2. Low residue diet.
3. Sulfasuxidine, 3 Gm. orally four times daily.
4. Streptomycin, 1 Gm. orally twice daily.

Operation is performed on the morning of the fourth day. With the patient supine and in deep Trendelenburg position, a lower abdominal transverse incision is made at the level of the

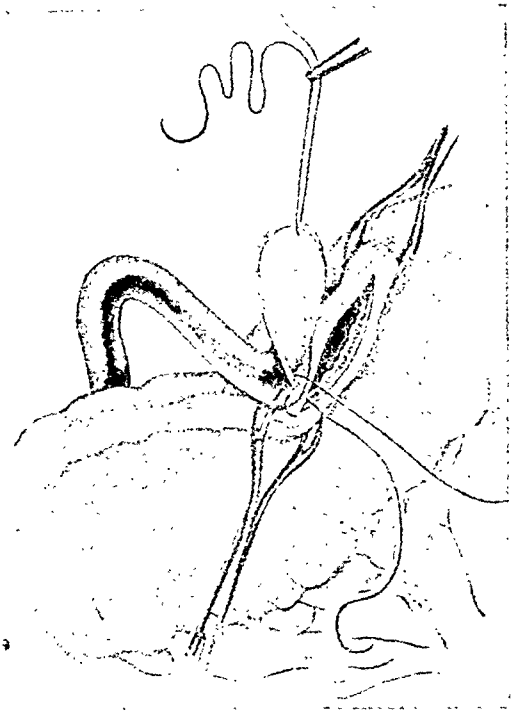

FIG. 5. Anastomosis readily accomplished, contiguous surfaces being of identical shape.

anterior superior spines, extending to the lateral border of each rectus muscle. Both rectus muscles are transected and the peritoneum opened. After packing off the small bowel, the ureter is identified just below the pelvic brim, the peritoneum overlying it incised, and the ureter picked up in a Babcock forceps. The ureter is then incised longitudinally on its posterior medial surface for a distance of approximately 1 to 1.5 cm. An appropriate portion of the sigmoid is then picked up between Babcock forceps and

FIG. 6. Diameter of ureter not impinged on by constriction of connecting stoma.

accurate estimation of the exact implant site determined by coapting the ureter, sigmoid, and the parietal peritoneum in such a position that all structures will lie in the pelvis with no constriction or acute angulation when final fixation is performed.

The bowel is next incised longitudinally along the lateral taenia for a distance of 1 to 1.5 cm. Anchor or approximating sutures are then placed. The first of these sutures passes through all layers of the ureteral wall at the proximal end of the ureteral incision and then through all layers of the bowel at the superior margin of that incision. The second anchor stitch joins the distal portion of the ureteral flange to the inferior end of the bowel incision (Fig. 7). When slight traction is applied to these sutures, the edges of the bowel and ureter are brought into close apposition, facilitating the accurate placing of sutures. A grooved director inserted in the ureteral canal often aids in the accurate placing of sutures adjacent to the proximal anchor stitch. Anastomosis is then completed using 5 zero chromic catgut, either by interrupted technic or a running suture (Fig. 8).

Finally, the anastomotic site is anchored firmly to the lateral pelvic peritoneum in such a way as to preclude angulation or traction upon the

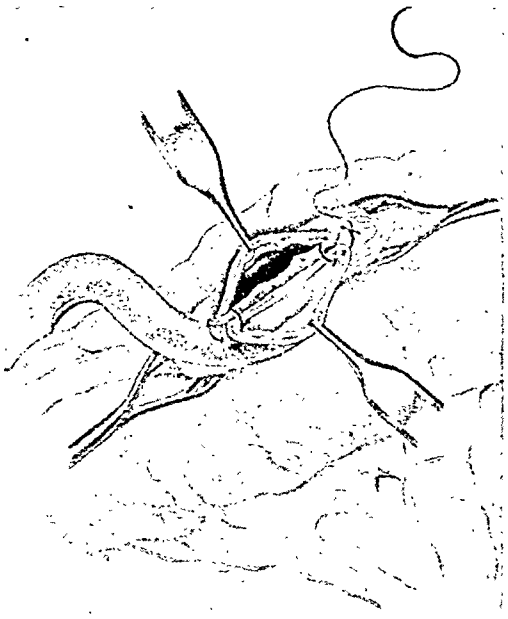

FIG. 7. Distal portion of ureteral flange is joined to inferior end of bowel incision by second anchor stitch.

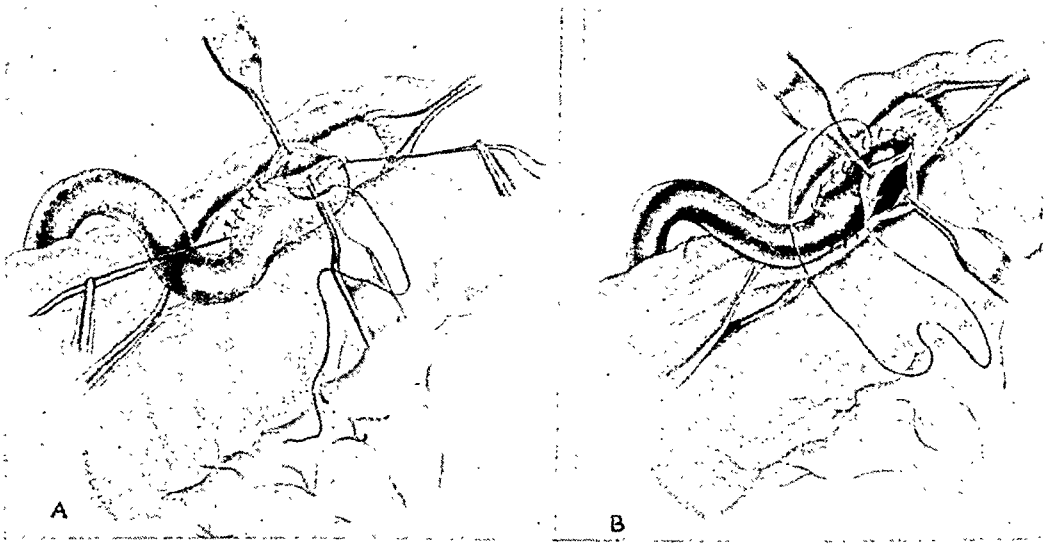

FIG. 8. Anastomosis completed with 5 zero chromic catgut using interrupted (A) or running sutures (B).

ureter. This is very important and should be performed with great care in all cases.

Following transplantation of the right ureter, the left ureter is handled in an identical fashion, providing there is sufficient mobility of the sigmoid. In some cases, however, mobilization of the colon is not sufficient to permit an easy lateral approximation of structures, and anastomosis is more readily accomplished by bringing the ureter through an opening made in the mesosigmoid, thus preventing angulation of the ureter and facilitating the connection. Fixation of the sigmoid must be carried out on the left side as it is on the right.

Cystectomy, when indicated, is now performed through the same abdominal incision. Closure is accomplished after insertion of two penrose drains into the retroperitoneal pelvic space, but no drains are left in the peritoneal cavity.

Postoperative care necessitates the use of an inlying rectal tube as a means of urinary drainage. Experience has shown that a dePezzer or Malecot catheter placed just inside the anus is the safest procedure. Unfortunately, one patient in the series that has been performed at the University Hospital suffered an anterior perforation of the rectum postoperatively due to the careless reinsertion of the ordinary type rectal tube. A mushroom type tube is now used as it accommodates itself readily to peristaltic action and remains fixed at the most distal portion of the bowel.

Other factors in the after care include ambulation on the second day, low residue diet as soon as tolerated, and streptomycin and sulfasuxidine for a period of one week.

Experience has shown that many patients following ureterosigmoid anastomosis develop acidosis from loss of base, regardless of the type connection used. Not only does the carbon dioxide combining power fall, but at the same time there occurs an elevation of the nonprotein nitrogen. The patient complains of anorexia, nausea, malaise, and a sense of impending disaster. At times this electrolyte loss may be quite severe, necessitating administration of intravenous fluids. While the mechanism of this chemical imbalance is not fully understood, it has been found to be readily corrected by the administration of additional base to the diet. A convenient form is either sodium bicarbonate or sodium citrate given in daily doses of 4 to 8 Gm. On the other hand, administration of too much base may lead to a relative alkalosis which, peculiarly enough, gives rise to the same symptoms. After the acidosis has been corrected, it has also been found that the nonprotein nitrogen rapidly returns to a normal value.

Mention should also be made of the observation that postoperatively these patients frequently take great pride in their ability to retain the urine in the bowel for prolonged periods of time. This accomplishment is to be deplored, since, evidently, gaseous reflux with ascending infection is far more prone to occur under this circumstance than if the colon is emptied promptly. These patients, therefore, should be instructed to evacuate the bowel every three to four hours.

Conclusion

The direct elliptic connection described above possesses some distinct advantages over the other technics that have previously been employed.

It provides for maximal diameter of the ureterosigmoidal opening. The elliptic shape counteracts concentric fibrosis and maintains a diameter three times that of the tubular ureter.

It assures freedom from ureteral stenosis with uninterrupted output of urine. The close apposition of the sutured edges together with through-and-through suture technic and thorough preoperative bowel preparation greatly decreases the chances of leakage and infection.

It permits the safe transplantation of dilated ureters.

Discussion

Carl Aberhart, M.D., *Toronto, Ontario, Canada* (*By invitation*).—I cannot concur with the author's view that dilated ureters cannot be transplanted by means of the Coffey technic. The only factor limiting the size of ureter which can be transplanted by this method is the transverse diameter of the colon. Various modifications of technic in these cases must be utilized.

The greatest single problem in the transplantation of ureters is the change which occurs postoperatively in the upper urinary tract due to lower ureteral obstruction. The site of this stenosis I am not prepared to discuss at this time.

Let me demonstrate to you these unfortunate changes which, in my hands, occur in the Coffey 1 type of transplant in approximately 75 per cent of cases. (*Slides shown.*) You will note two very important points: first that the hydroureter and hydronephrosis occur early and second that once established are constant and progressive. In our series I have never seen a hydronephrosis and hydroureter disappear.

This fact caused us much concern. We were convinced that cancer of the bladder should be treated by the application of general surgical principles, namely, ureterointestinal transplantation and total cystectomy, but we did not feel justified in replacing a known lethal disease, such as cancer, with an equally lethal disease in the form of pyelonephritis.

Many modifications were made in our technic, using Coffey type transplants, with uniformly unpredictable results. It was not until Dr. Nesbit reported to the genitourinary surgeons in May, 1948, his method of direct elliptic anastomosis that any satisfactory results seemed possible.

Since May, 1948, I have operated on 35 cases for the purpose of ureterointestinal transplantation, with or without cystectomy, by the Nesbit technic. Through experience we have found there are several points in the operation which should be emphasized. First, the preparation of the ureter must be such that there will be no looseness or slack in the ureter following completion of the anastomosis. The ostium of the ureter must be at least 1 to 1½ cm. in circumference. I would suggest to you that it is impossible to have too large an ostium and that, to be safe, always make it ¼ cm. larger after you feel it is large enough.

The ureter should be sutured to an opening in the rectosigmoid which is situated between the taenia or longitudinal bands. In our experience ureters transplanted into the taenia have become obstructed. This principle, as you will realize, is the direct opposite to that employed in Coffey type transplantations.

Following the anastomosis, the colon must be firmly immobilized to the lateral pelvic wall. We have found that 5 zero chromic catgut is not sufficiently strong for this purpose. We now use ordinary curved gastrointestinal suture.

There is one further point associated with this operative procedure which I should like to bring to your attention. I believe it unwise to attempt this type of anastomosis in patients whose ureters show evidence of acute ureteritis or where the clinical findings have suggested acute pyonephrosis or pyelonephritis due to lower ureteral obstruction. One such case was transplanted with a resulting urinary-fecal fistula appearing on the fifth day.

It would not be fair to conclude my remarks without telling you that, in my opinion, we have not yet reached the total answer to the satisfactory solution of ureterointestinal transplantation. The cause of the postoperative complications of nausea and distaste for food, occurring within a few days of operation, must be discovered. The reason for lowered carbon dioxide combining power occurring in later stages must be sought. It is likely that the whole biochemistry of the individual with urine in the lower colon will have to be studied.

It is my opinion, however, that the anatomic and functional results of ureterointestinal anastomosis, performed by direct elliptic suture, are consistently superior to those obtained by any other method. For this reason, this operative procedure must be mastered and included in the surgical armamentarium of all doctors dealing with serious lesions of the lower urinary tract.

ETIOLOGY AND TREATMENT OF PANCREATITIS

HENRY DOUBILET, M.D., F.A.C.S., and JOHN H. MULHOLLAND, M.D., F.A.C.S.,
New York City

(From the Department of Surgery, New York University College of Medicine, and the Third (New York University) Surgical Division, Bellevue Hospital)

PANCREATITIS is a common disease frequently unrecognized because it simulates other acute upper abdominal conditions. It can usually be diagnosed easily if the possibility of its presence is considered and if routine serum amylase determinations are done in all such conditions. The diagnosis of acute pancreatitis is important because operation should never be done during the acute phase.[1-3]

An understanding of the etiology and pathology of the disease is based on the following points:

1. A common passageway is present between the bile and pancreatic ducts. Spasm of the sphincter of Oddi or, rarely, a stone impacted in the papilla will enable bile to enter the pancreatic ducts.[4,5] This common passageway was found in the great majority of our cases.

2. An emotional disturbance is the usual cause of spasm of the sphincter of Oddi (Fig. 1).

3. The inflammation of the pancreas is initiated by the bile salts present in the bile. This was proved by Flexner in 1906, and confirmed by Archibald, Dragstedt, Ireneus, and Wangensteen.[4,6-9]

4. Alkalinization of the bile salt solution by pancreatic juice renders it toxic and causes reactive edema and necrosis.

5. Necrosis and hemorrhage, which sometimes follow the initial edema produced by the bile salts, are due to the action of trypsin which has been activated by dead cells and exudate.

6. The local effects of acute inflammation of the pancreas may result in the following:

(*a*) Obstructive jaundice which is transient when due to swelling of the head of the pancreas. The bile duct may become tortuous and narrowed and even completely obstructed when the head of the pancreas becomes fibrosed, enlarged, and irregular (Fig. 2).

(*b*) Acute and chronic diabetes—A transient severe diabetes associated with severe acidosis and glycosuria may occur during periods of acute edema. With advanced destruction of the pancreas, a chronic diabetes may develop.

(*c*) Normal restitution—The attacks of edematous inflammation may resolve, and at a

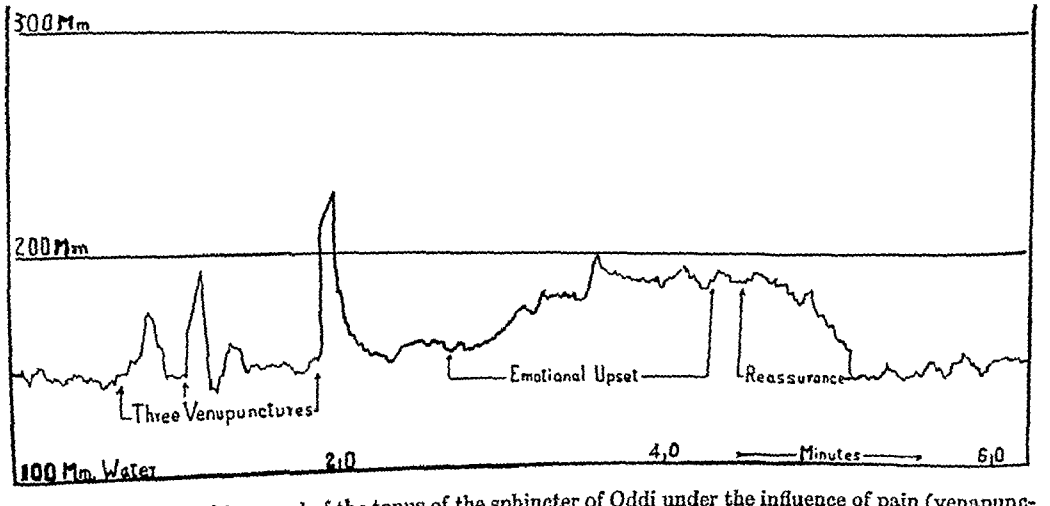

FIG. 1. Kymographic record of the tonus of the sphincter of Oddi under the influence of pain (venapunctures) and emotion. The increased tonus resulting from a feeling of hostility and resentment rapidly subsided on reassurance.

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo, Section on Surgery, May 6, 1949.

FIG. 2. Postoperative cholangiogram through the gallbladder in a patient who developed jaundice with each attack of pancreatitis shows marked constriction of the common duct at one point (arrow) with distortion and narrowing below that point. Marked dilatation of the biliary tract above the inflammatory stricture is present.

later date the pancreas will be found normal by direct observation at operation.

(*d*) Complete necrosis of the pancreas—A generalized hemorrhagic necrosis may lead to death due to large losses of fluids into the peritoneal cavity.

(*e*) A pancreatic cyst may replace a localized area of necrosis.

(*f*) Chronic pancreatitis—Recurrent attacks producing localized necrosis will lead to fibrosis and gradually destroy the pancreas. The loss of pancreatic juice will eventually result in steatorrhea, inability to digest food, or to maintain normal weight.

(*g*) Calcification of the pancreas—Under certain conditions, calcium carbonate stones will form in the pancreatic ducts and lead to obstruction, fibrosis, and loss of pancreatic juice secretion.

(*h*) Widespread inflammation of the upper part of the abdominal cavity followed by formation of adhesions, fibrosis and calcification. —The exudate from the inflamed pancreas pours out through the foramen of Winslow and involves the gallbladder, liver, transverse colon, and duodenum in a massive inflammatory exudate which eventually leads to fibrosis and adhesions. It may spread down the right lumbar gutter and involve the whole peritoneum, producing a paralytic ileus, with x-ray evidence of distended small bowel with fluid levels. Accumulation of fluid beneath the diaphragm may lead to subphrenic abscess. Areas of fat necrosis may become calcified and these calcific nodes may be found on the gastrohepatic omentum, on the liver, and on the mesentery throughout the peritoneal cavity.

(*i*) Varicosity of the portal system may occur as a result of the narrowing or occlusion of the portal vein due to the surrounding fibrosis.

7. General effects produced by acute inflammation of the pancreas:

(*a*) The serum amylase is elevated due to absorption into lymph and blood from the inflamed organ. In a mild attack the rise is transitory; in a severe attack it may last a week. If the pancreas is fibrosed and partially destroyed as a result of recurrent attacks, the serum amylase may be normal or low. A high serum amylase is diagnostic; a low figure does not exclude pancreatitis. Serum lipase is also elevated but is not usually measured because of technical difficulties.

(*b*) Elevation of serum trypsin is probably present but cannot be measured. Its presence is indicated by (1) injury to the cardiovascular system, as evidenced by electrocardiographic changes, occasionally by transient hypertension, and sometimes by vascular thrombosis, occasionally involving the brain; (2) injury to the liver and to the kidneys; and (3) subcutaneous hemorrhages.

8. Pain in recurrent pancreatitis is produced by two mechanisms:

(*a*) Distention of the biliary pancreatic ducts due to hypertonicity of the sphincter of Oddi—Epigastric and back pain radiating to the right (biliary) and to the left (pancreatic) is either intermittent or continuous; early in the disease it may occur only during an acute attack. Food always produces or aggravates the pain. Section of the sphincter of Oddi abolishes this pain.

(*b*) Inflammatory pain—This occurs during an acute attack and is severe, persistent, and frequently localized in the right upper quadrant where the inflammatory exudate first comes in contact with the parietal peritoneum. The pain lasts from twelve hours to two weeks if the patient is not treated adequately.

9. Other causes of acute pancreatitis—Mumps and possibly other virus diseases may cause inflammation of the pancreas. Alcohol may be a special causative factor in pancreatitis; if so, the mechanism of its action on the pancreas is still unknown.

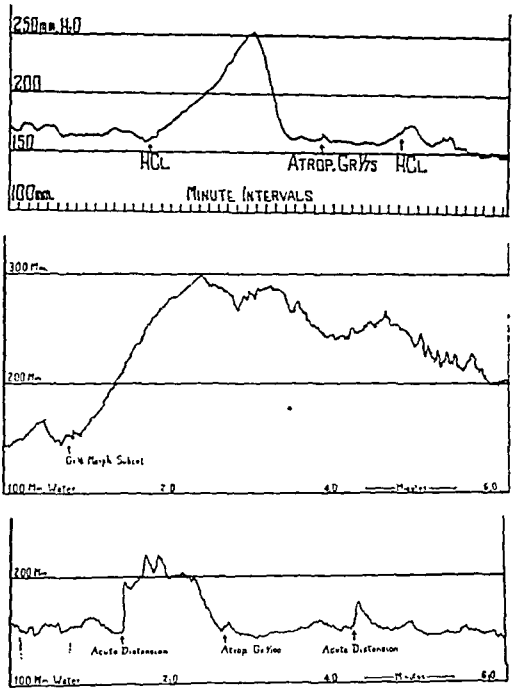

FIG. 3. Kymographic records of the tonus of the human sphincter of Oddi show that acid (locally applied), morphine, and acute distention of the biliary tract produce spasm. Atropine abolishes this reflex to acid and to distention but does not influence the effect of morphine.

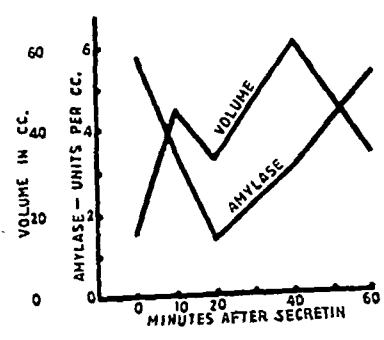

10. Spasm of the human sphincter of Oddi can be produced deliberately by (1) acid, (2) morphine, and (3) acute distention of the biliary tract through a T-tube (Fig. 3).[10] These procedures are useful in cholangiography, since the presence of a common passageway can be demonstrated by visualizing the pancreatic duct. Morphine produces spasm of the duodenal wall as well. It is useful in proving that the one-way valve action of the duodenal wall which prevents duodenal reflux and cholangitis is intact after sphincterotomy. This complication has not occurred in any of our patients after sphincterotomy.

Diagnosis of Pancreatitis

Acute Phase.—A high serum amylase is diagnostic and differentiates pancreatitis from perforated ulcer, acute cholecystitis, intestinal obstruction, mesenteric thrombosis, or cardiac infarct. A low serum amylase does not exclude pancreatitis. A history of repeated attacks or of a previous operation in which pancreatitis was found is of help. Frequently, a diagnosis can be made only by exclusion after the attack has subsided.

Interval Phase.—The diagnosis depends on (1) the history, (2) the type of pain, (3) exclusion of other upper abdominal diseases, (4) evidence of calcification of the pancreas, (5) a diminished secretin test (Fig. 4), and (6) steatorrhea—presence of undigested food in the stools and failure to gain weight on an adequate intake.

Recurrent pancreatitis is the most common cause of postcholecystectomy attacks of pain. A normal secretin test may be found even after a long history of recurrent attacks. It is wise to watch such patients until a high serum amylase is finally discovered during the height of one of the attacks. However, serious loss of weight due to

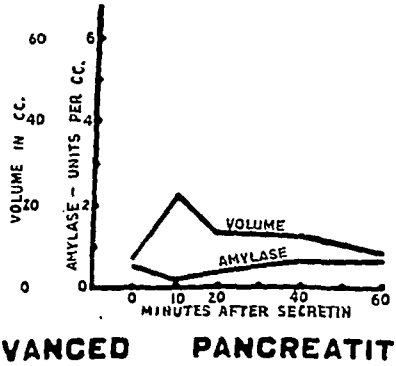

FIG. 4. Typical secretin tests—17 mg. secretin (Lilly) injected intravenously.

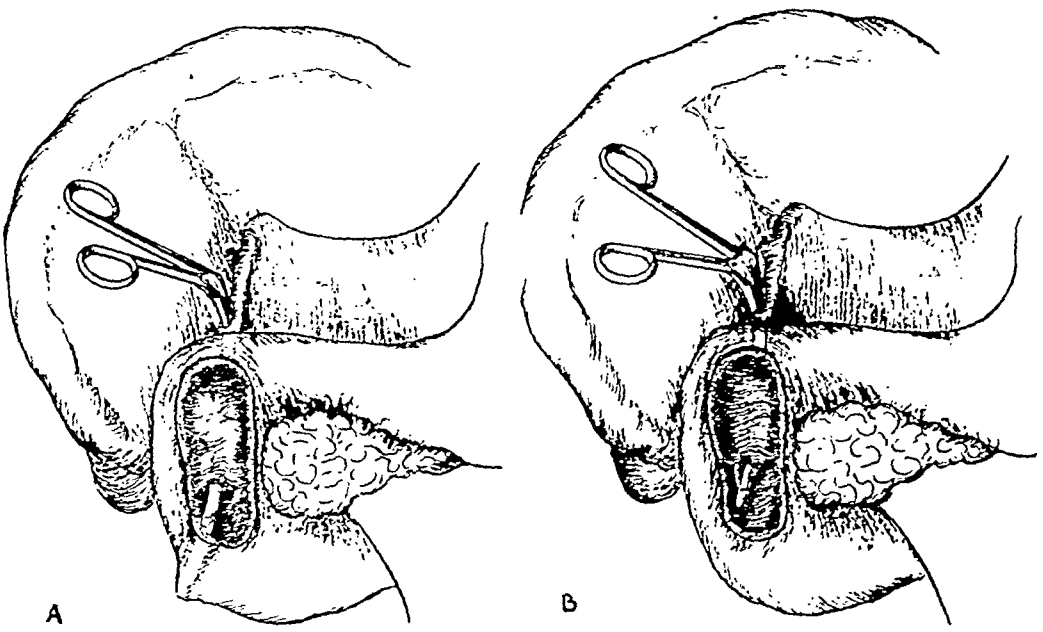

FIG. 5. Endocholedochal sphincterotomy. (A) The sphincterotome is inserted through the common duct into the duodenum until it elevates the anterior duodenal wall. (B) The blade is then opened and the instrument retracted until it hooks the anterior free lip of the papilla. On closure the sphincter of Oddi is sectioned.

fear of pain on eating may force the issue at times.

Treatment of Recurrent Pancreatitis

Acute Phase.—Operation is contraindicated. The treatment is based on the following principles:

1. Shock and dehydration are treated by intravenous blood, saline, glucose, and amino acids.

2. The pancreas is put at rest by stopping all oral feeding. Continuous Wangensteen suction is used to prevent acid from entering the duodenum and so stimulating the pancreas by the formation of secretin. Paralytic ileus, if present, is also controlled. Atropine, $^1/_{150}$ grain every six hours, also helps to reduce the activity of the pancreas.

3. Penicillin is given to prevent infection of the exudate and any necrotic tissue present.

4. Treatment of acute diabetes if present. Emergency blood sugar and carbon dioxide combining power should be tested, even if the urine is sugar free. Large doses of insulin are sometimes required to overcome the acidosis.

5. Rapid subsidence of the pain results from the above measures. At most, small doses of Demerol are required. Morphine is never used.

Surgical Treatment.—When the patient has recovered from the acute attack, careful x-ray studies of the gallbladder, stomach, and duodenum are done. A secretin test to determine external pancreatic secretion and a glucose tolerance curve to exclude the possibility of diabetes are also performed.[11] Serum protein and prothrombin time are checked.

PREOPERATIVE PREPARATION.—A Rehfus tube is passed one hour before operation. Medication consists of Demerol and atropine. General anesthesia is preferred.

OPERATIVE PROCEDURE.—Through a right upper transverse abdominal incision, the cystic duct is dissected out and a rubber strip passed around it to steady it and close off the gallbladder. Cholangiographic studies are carried out through a needle inserted into the cystic duct. In the absence of the gallbladder, the needle is inserted into the common duct. Ten cubic centimeters of one-tenth normal hydrochloric acid are injected through the Rehfus tube to cause spasm of the sphincter of Oddi and so enable the diodrast to enter and visualize the pancreatic duct. The gallbladder is then removed; the common bile duct is opened supraduodenally and the sphincter

of Oddi cut endocholedochally if the sphincterotome enters the duodenum readily (Fig. 5).[12,*] The common duct is then closed and a small rubber tube placed down to it. If the instrument is arrested at the papilla, a 3-mm. incision is made in the anterior duodenal wall over the tip of the instrument. By pushing the anterior duodenal wall dorsally over the tip, the papilla riding on the end of the instrument is made to protrude through the small incision. The sphincter is sectioned under vision. The instrument is then withdrawn and the opening in the duodenal wall closed by a pursestring suture reinforced by another layer.

Postoperative Treatment. — Continuous Wangensteen suction is kept up for two days. The patient is supported by intravenous glucose, saline, and amino acids. Water is given by mouth on the second day, fluids on the third day, and a soft diet (fat free) on the fourth day. The rubber drainage tube is removed on the third day.

A T-tube is placed in the common duct in patients who are to be studied for proof that sphincterotomy (1) destroys the function of the sphincter, (2) prevents pancreatic reflux, and (3) does not permit duodenal reflux by retaining the one-way valve action of the duodenal wall. The T-tube is tied off on the fourth day since the bile flows into the intestine with minimum resistance. On the tenth day, cholangiographic studies are done to confirm the absence of any residual stone, to show that the sphincter does not react to acid, and to prove that the duodenal wall is intact. The next day kymographic tracings are done to confirm these observations.

Case Reports

Case 1 (*Treatment of Severe, Acute Recurrent Pancreatitis with Many Complications*).—F. R. was a twenty-seven-year-old woman with a three-year history of recurrent attacks of severe, midabdominal pain radiating to the epigastrium and left upper quadrant, occurring at varying intervals from daily to monthly, lasting from two hours to one week and accompanied by fever and tenderness in the epigastrium and left upper quadrant. Her last attack started five days before admission to the Third (New York University) Medical Division of Bellevue Hospital, October 9, 1947. Examination at this time revealed jaundice (icteric index 22, bile in urine); paralytic ileus (distended small bowel with fluid levels by roentgen ray); diabetes with acidosis (blood sugar 250 mg. per cent, sugar and acetone in urine, carbon dioxide combining power in blood, 30 volume per cent); hypertension (blood pressure 158/96); albumin in urine; and serum amylase over 300 mg. per cent.

Under treatment by intestinal suction, atropine, intravenous fluids, and insulin, all symptoms disappeared within one week. A cholecystogram three weeks after onset of attack visualized the gallbladder. Roentgenogram of the stomach and duodenum showed normal findings. The patient was transferred to the surgical service on November 1, 1947. A secretin test showed diminished pancreatic function (volume 91 cc., amylase 92 units). At operation on November 7, 1947, a thin-walled gallbladder surrounded by dense adhesions was found; the pancreas was hard, enlarged to at least twice its normal size, and showed areas of old diffuse hemorrhage beneath its capsule. A cholangiogram visualized the pancreatic duct. The common bile duct was very narrow. After cholecystectomy, the duct was opened and a fine probe passed into the duodenum, which was opened over the probe. The sphincter was sectioned and a fine catheter passed up the bile duct and out through the lateral angle of the wound. The duodenum was then closed. The catheter was dislodged accidentally on the fourteenth day, and a cholangiogram, performed immediately afterwards through the fistula, visualized the pancreatic duct. The fistula closed the next day, and the patient was discharged sixteen days after operation.

Histologic examination of a biopsy of the pancreas showed a marked inflammatory reaction and replacement of acinar tissue by extensive fibrosis.

The patient has been asymptomatic since operation, in spite of relapsing to old habits of periodic alcoholic sprees. When last seen one and one-half years after operation she had gained 20 pounds in weight.

Case 2 (*Persistent Severe Postprandial Pain and Loss in Weight Following Cholecystostomy for Acute Pancreatitis*).—C. R. was a twenty-nine-year-old woman with a six-year history of recurrent monthly attacks of severe epigastric pain associated with nausea and vomiting and radiating to both upper quadrants and to the back. Repeated roentgenograms of the gallbladder, stomach, and duodenum showed no abnormality. Exploratory laparotomy at another hospital during an acute attack in 1943 revealed acute pancreatitis. Cholecystostomy and drainage of the pancreas were performed. Drainage from the cholecystostomy site persisted intermittently for the intervening five years and, at one time during the course of this biliary drainage, a small cholesterol stone was extruded. When the fistula closed, the attacks recurred.

She was admitted to this hospital on February 15, 1948. Contrast medium injection of the fistula revealed a small cavity which appeared to hold a radiotranslucent stone. The drainage fluid contained no amylase. A secretin test showed marked reduction in the pancreatic function (total volume 42 cc., total amylase 43 units). At operation on February 25, 1948, the fistula was found to communicate with a markedly fibrotic gallbladder containing a stone impacted in the cystic duct. The common bile duct was at least twice its normal size. The pancreas was hard throughout and moderately enlarged. A cholangiogram visualized the whole pancreatic duct

* Manufactured by the American *Cystoscope* Makers, New York.

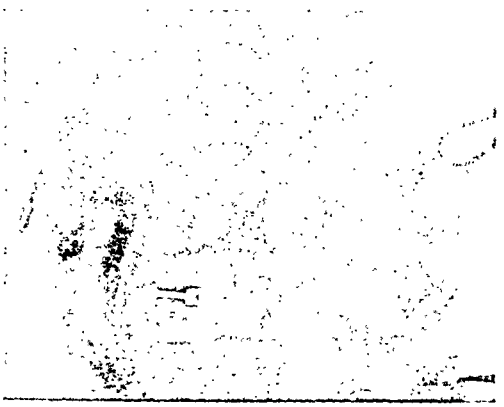

FIG. 6. Operative cholangiogram (Case 2) in which the pancreatic duct (arrow) was visualized as a result of spasm produced by acid.

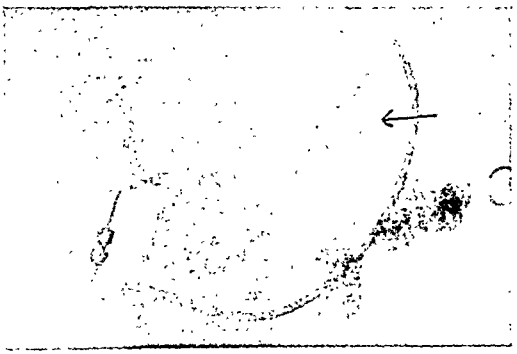

FIG. 7. Operative cholangiogram in patient with calcification of pancreas (Case 3). The distended common bile duct becomes narrow and tortuous in its passage behind the enlarged, fibrosed, and calcified pancreas (arrow).

(Fig. 6). Cholecystectomy and endocholedochal sphincterotomy were performed. The common duct was closed and a small drain, which was removed four days after operation, placed down to it. The patient has been completely symptom free since operation.

Case 3 (*Chronic Pancreatitis with Calcification Resulting from Recurrent Attacks; Previously Treated by Cholecystostomy*).—D. R. W. was a forty-year-old white man with a twelve-year history of attacks of severe epigastric pain radiating to the back and to both upper quadrants, occasionally accompanied by vomiting. The attacks lasted from two hours to two days and at first occurred about every six months, but in the last few years the severe attacks occurred every few weeks and he had had pain after eating almost every day. Ten years ago a diagnosis of perforated ulcer was made, but no operation was done. Between 1940 and 1944, he was admitted to four different military hospitals. Many roentgenograms showed a normal gallbladder and normal stomach and duodenum. He was finally discharged from the Army on February 11, 1944, because of incapacitating pain. No diagnosis was made. Examination by a civilian physician revealed calcification of the pancreas. A cholecystostomy was performed, but by request of the patient the pancreas was not removed. He had no pain as long as the cholecystostomy was functioning. As soon as the drainage tube was removed the attacks of pain recurred. A secretin test done on April 12, 1948, revealed marked impairment of the pancreas (total volume 120 cc., total amylase 65 units).

At operation on April 16, 1948, the pancreas was found to be large and very hard with an irregular, knobby surface. The gallbladder was removed. A cholangiogram showed the common bile duct to be about twice its normal size above the duodenum and very tortuous and narrowed below, owing to its passage behind the fibrosed, enlarged irregular head of the pancreas (Fig. 7). The common duct was opened, the sphincterotome passed into the duodenum, and sphincterotomy done. The common duct was sutured, and a small drain placed down to the line of suture. He has had no pain since his operation, but the function of his pancreas has not improved. Steatorrhea is present. It is controlled by large doses of pancreatin and bile salts. On this regimen he is gaining weight.

Summary and Conclusions

Pancreatitis is a common disease frequently undiagnosed because routine serum amylase determinations are not done in all acute upper abdominal conditions. Frequent use of the secretion test would also increase the number of recognized cases, especially in the group diagnosed as postcholecystectomy syndrome or biliary dyskinesia.

The main causative factor is reflux of bile into the pancreas as a result of spasm of the sphincter of Oddi. Section of this sphincter prevents further biliary reflux and arrests the disease. Preservation of the duodenal musculature surrounding the bile duct prevents ascending cholangitis.

Discussion

John J. Morton, M.D., *Rochester.*—Acute pancreatitis must be considered as a possibility in patients complaining of severe epigastric pain. Even the most experienced clinicians cannot with certainty make a differential diagnosis on such a patient without the assistance of laboratory procedures. Attempts to rule out perforated ulcer should be carried out by x-ray examination. Fulminating biliary tract infection is difficult to evaluate, as 60 per cent of these patients show icterus. Electrocardiographic changes may be noted suggestive of myocardial infarction or coronary thrombosis, but the upper abdominal peritoneal irritation and elevated blood amylase establish the diagnosis of acute pancreatitis. In fact, until we had Somogyi's rapid amylase test we were in the dark on many of these acute cases. The result was surgical exploration with a high mortality. The serum amylase test should now be routine for every acute abdominal emergency. The test takes twenty to thirty minutes. If the serum amylase is over 200, it is beyond the normal range and points strongly to the pancreas. Once the diagnosis is established, watchful waiting should be the rule until the process has subsided, usually within one week. Then, study of the biliary tract and operation will prevent recurrence of acute pancreatic episodes in most instances. These operations usually mean cholecystectomy and exploration of the common duct because small stones passing down the duct and blocking the papilla cause reflux of bile into the pancreatic duct in most cases. This is either due to the 10 per cent common channel or to spasm of the sphincter of Oddi. Bakes dilators should be used to be sure that the sphincter has been well stretched.

If operation is not done following subsidence of an acute pancreatic attack, the patient may have another attack later; and some go on having attack after attack until something is done to prevent them.

Elman recommends nitroglycerin and gives his patients 1/100 grain tablets to help abort attacks by relaxing the sphincter of Oddi at the start.[1,2] Gage advocates bilateral splanchnic block to relieve the spasm in the acute attack, repeating if necessary.[3] Others have claimed relief by paravertebral block in the eighth to tenth dorsal segments or by vagotomy.[4] Leriche in 1934 records a case in which he made a direct incision into the pancreatic duct and drained it for chronic pancreatitis.[5] Twenty years later he repaired the hernia in the abdominal wall. He wrote that this "was the fortunate ignorance of youth—today, I would take out the gallbladder and drain." In a recurrent attack of pancreatitis in a badly diseased pancreas, Caleb Smith, and Pearse decided to tie off the pancreatic channel so that reflux could not occur.[6] This resulted in freedom from attacks.

The direct attack on the sphincter is rational. Its spasm is undoubtedly a factor of importance. The approach through the common duct is logical, although direct attack by a transduodenal operation might prove more accurate.

The clinician must be able to differentiate between the acute edematous pancreatitis and the hemorrhagic pancreatic necrosis. The former calls for delay and subsidence of the attack, the latter for action, since delay is fatal. Only close clinical observation and judgment will make it possible to tell when the patient remains ill and does not respond as he should to the edematous type. Fine states that when the amylase reading is high (2,000 or over), he operates, but this has not been our experience.[7] Some of the highest readings have quickly subsided to normal within a few days, and the patient gets well.

Many patients who have severe attacks sustain pancreatic damage which shows up later. If followed long enough, a definite proportion will show diabetes. Shumacker found that, of those surviving, from 3 to 10 per cent had diabetes.[8] Repeated recurring attacks should be avoided in order to spare all the pancreatic tissue possible.

MATERNAL MORTALITY RATES DROP AGAIN FOR 1948

A continuation of the downward trend in maternal mortality shown by rates of 1947 is indicated by provisional figures for 1948 collected from state public health agencies by the American Medical Association.

The United States undoubtedly will show a rate of not more than 1.2 maternal deaths per thousand live births in 1948, a drop of 0.1 from the previous year, according to an editorial in the October 1 issue of the *Journal of the American Medical Association.*

Since 1933, the United States has made tremendous progress, with the rate declining from 6.2 to 1.2 in fifteen years; in 1947 the rates for whites and nonwhites were 4.5 (5.6 — 1.1) and 6.4 (9.7 — 3.3) lower than in 1933. The spread between the highest and lowest state rates decreased from 7.2 (11.5 — 4.3) in 1933 to 2.3 (2.7 — 0.4) in 1948. More important than the decline for the whole nation is the fact that the highest state rate in 1948 was 2.7, which was less than two thirds of the rate, 4.3 for the best state in 1933.

To the extent that this one vital statistic can be considered an index of health, the charge that rapid improvement in health has been limited to the wealthier sections of the country is clearly and emphatically refuted.

DIABETES CONTROL IN THE PUBLIC HEALTH PROGRAM

HUGH L. C. WILKERSON, M.D., Boston, Massachusetts

(From the U.S. Public Health Service, Division of Chronic Disease, Diabetes Branch)

THE problem of diabetes mellitus is a serious matter. Its relationship to the occurrence of cardiovascular disease, particularly arteriosclerosis, blindness, and other diseases including the nephritides demands that more attention be given to it by clinicians, health officers, and research workers.

This presentation attempts to describe one concept of the responsibility of the community for assistance in the control of diabetes mellitus. A practical plan of action is now being demonstrated.

What is meant by the statement that diabetes is a public health problem?[1] What is public health? The general concept of public health today is that it deals with the prevention of disease, the prolongation of life, and the promotion of mental and physical efficiency through organized community effort. What is diabetes control? Before the discovery of insulin, the average life expectancy of a child with diabetes was about two years with the best treatment known.[2] A diabetic adult lived on an average about eight years. It was difficult to manage diabetes in the individual clinically, and starvation diets provided the major control measures. Public health measures were not adaptable to the diabetes problem at that time.

Significant changes have occurred in comparatively recent years. With advances in insulin and diet therapy, the juvenile diabetic can now look forward to an ever-increasing life span. If the adult diabetic today is recognized early and he gets all the benefits of our present medical knowledge, he may expect to have a longevity which approaches that of the average American citizen of his age. Early detection improves the prognosis and offers encouragement for the prevention of complications. Prompt and aggressive therapy by a competent physician usually foreshadows successful treatment and a happy life. The proper psychologic presentation of the treatment pattern encourages the individual and stimulates good mental adjustment to the required changes in habits. This, together with comprehensive education of the diabetic individual in feasible methods of self-management, promotes both his mental and physical well-being.

Progressively more encouraging results are being obtained in the reduction of deaths and the prevention of illness due to acute infectious diseases, particularly in the younger age groups. Public health programs, however, have given very little, if any, attention to diseases of a chronic nature affecting the older age groups. Conditions more commonly found in middle age and later adult life, such as cancer, heart disease, and diabetes, have been showing a steady increase in morbidity and mortality year by year.

There are significant factors which may be responsible for this increase:

1. Life expectancy has been increased from 49.2 years in 1900 to 65.8 in 1945. This means that comparatively large numbers of people will reach an age at which they are particularly susceptible to diseases such as cancer, heart disease, and diabetes.
2. Better diagnostic measures are available, and their use has become more general.
3. There is reason to believe that obesity or overnutrition in relation to body needs may have brought a true increase in diabetes.

It is reasonable to assume that one reason for the lack of success in the prevention and control of diseases among older age groups is due to the fact that little has been done by organized community effort and health departments in the promotion of adult hygiene.

Before considering whether organized community effort can give assistance, it may be well to review briefly some of the data about the prevalence of diabetes.

In 1947, a study was made in Oxford, Massachusetts, by the Diabetes Section of the Public Health Service.[3] Analyses of both blood and urine for sugar were made on 70.6 per cent of the entire population of 5,000. A total of 70 cases of diabetes was found. Forty of these cases consisted of previously known diabetes. The additional 30 cases were discovered during the survey. The prevalence of diabetes was 2 per cent of those tested. Authorities in the American Diabetes Association have applied these figures to the whole population of the U.S., estimating that there are probably more than two million people in our country with diabetes, half of them known and half unknown.

By 1985, it is estimated that the population of the nation will be at a maximum. It is predicted that by that time the general population will be increased by only 22 per cent, whereas the diabetic population will be increased about 75 per cent.[4]

Presented, by invitation, at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo, Section on Public Health, Hygiene, and Sanitation, May 5, 1949.

From a study of Joslin's patients who died between 1936 and 1943, it was found that 64 per cent of individuals known to have diabetes were classified as having died from it.[5] Eleven per cent of the individuals were classified as having died from some concurrent cause with diabetes as a contributory cause, and in 24 per cent of those known to have diabetes it was not mentioned on the death certificates. Altshuler reported similarly that only 58 per cent of a group of 142 known diabetics at death were recorded as having died of diabetes.[6]

The past trend in the death rate for diabetes is difficult to evaluate because the procedure used for classifying diabetes deaths for official statistics did not take into account the physician's opinion of the importance of diabetes relative to other concomitant diseases and conditions. Starting with 1949, it is expected that the recorded statistics will more nearly reflect medical opinion of diabetes as a cause of death. However, diabetes mortality statistics for 1949 and later years will not be comparable with those of earlier years.

For the above reasons conclusions based upon mortality are not given much attention in this discussion. It is the great prevalence of the disease and the seriousness of the increasing socio-economic problem of its complications to which emphasis is given.

In considering the matter of health and disease the question quite naturally arises as to when a health problem becomes one with which public health agencies should cope. It is believed that a health problem becomes a public health responsibility, when, because of its nature and extent, it is more amenable to solution by organized community action. There should be practical and easily available methods and procedures applicable through community action to the solution of that particular problem. The communicable diseases and such other activities as vital statistics, health education, and sanitation fit readily into this concept of public health. Questions arise, however, as to the extent to which public health programs should act in relation to problems of the sick individual.

Dr. Harry Mustard has this to say regarding the subject:

> One wealthy individual with diabetes, or a thousand pregnant women able to pay their way, do not necessitate any organized action for their care, and their problems would not, therefore, fall within the limits of the generally accepted concept of a public health problem. But a hundred diabetics uneducated as to the care of their feet, unable to buy insulin, or to pay a physician, or a thousand maternity cases with no funds for medical care, would necessitate organized action, whether by hospitals, by health departments, or by a privately operated clinic. The real question at issue, then, is not so much whether the person is well or ill, or even in the last analysis, whether rich or poor—for the rich use the sewerage system—but rather when, or if, a given problem of health and disease can no longer be solved by the unassisted effort of the citizen and the uncoordinated resources of the community.[7]

If we are convinced that most diabetics are (1) being detected reasonably soon after they develop the disease, (2) receiving the kind and amount of education which makes it possible for them to cooperate with their private physician in the control of their disease, and (3) receiving adequate medical care, then we have no public health problem. If, however, practicing physicians, health officials, and the public agree that these are needs in which organized community effort should give assistance, we are faced with the challenge of developing a community program.

How serious is diabetes as a public health problem? It probably is not possible to measure exactly the seriousness of a public health problem. However, criteria have been set forth which enable us to evaluate the problem relatively.[7] These criteria are discussed in relation to diabetes.

First, the median annual mortality rate is usually considered. The data are incomplete and confusing so far as reported deaths are concerned. For the country as a whole in 1946, diabetes was reported as causing one third more deaths among white women than tuberculosis. In 1920, according to recorded data, diabetes caused 1.2 per cent of deaths from all causes, and in 1940 this proportion had more than doubled—2.5 per cent of the total deaths. In other words, between 1920 and 1940 the rate of increase of diabetes as a cause of death was second only to heart disease. It is noteworthy too that a significant amount of arteriosclerotic heart disease is probably causally related to diabetes mellitus.

Second, consider the median annual morbidity rate. Reporting of diabetes is not required, but it has been estimated that new cases currently number at least 50,000 annually.[4] When the probabilities for each sex-age group are applied to the 1946 population of the United States, it is found that about 4,125,000 persons, or 2.9 per cent of this population, will eventually become diabetic.

As we have said, present therapy gives the juvenile diabetic more hope for an ever-increasing life span. Also, as noted before, the adult diabetic, recognized early and receiving the benefits of our present medical knowledge, has a life expectancy which approaches that of the average American citizen of his age. This represents

real progress in treatment and is encouraging for the diabetic; however, no cure is known for diabetes. That means his problem is with him for a long period of time—a most important factor in determining the seriousness of diabetes as a public health problem.

To be dealt with also, are the all too frequently occurring disabling complications of long duration diabetes, such as arteriosclerosis, neuropathy, retinopathy, and intercapillary glomerulosclerosis.

Third, we should take cognizance of the age group in which the forces of mortality and morbidity express themselves.

It has been stated by Mustard that, from a biologic and even from a sociologic point of view, deaths in old persons are not so serious a national problem as the same number of deaths in young adults.[1] He further states, however, that to work out a formula establishing relative values of life at various ages would involve arbitrary decisions so numerous as to invalidate conclusions.

Diabetes, however, is by no means a disease confined to the aged. Therefore, when the criteria just discussed are applied to diabetes, it may be safely stated that it is a public health problem of a magnitude sufficient to warrant our serious attention.

With reference to age distribution of diabetes, Joslin points out that discussions of prevalence and incidence are misleading.[2] In analyzing over 10,000 diabetes case records for age-of-onset of the disease, he reveals that about one fourth of the cases became diabetic before thirty years of age and about one half between the ages of thirty and fifty-nine years. These findings led him to conclude that "diabetes is not an old age disease" and that there is "a declining susceptibility in the latter decades of life."

Factors in the Makeup of the Public Health Program

It would seem logical for health departments to balance their programs of prevention and control in relation to the seriousness of the various diseases. However, this is not always possible, because often the scientific knowledge necessary for prevention and control of the condition is not yet available or is not applicable to the problem. In the case of diabetes, however, we do have sufficient knowledge to launch a program which would aid substantially in the prevention and control of the disease.

The problem is not too disseminated or masked as to make detection of early and potential cases impractical. There is a favorable attitude on the part of the public. The medical profession, particularly through the magnanimous work of the American Diabetes Association, is sponsoring and encouraging the fullest possible application of scientific knowledge concerning the disease. The American Diabetes Association is energetically stimulating practicing physicians to become awakened to their own responsibility in this public health problem.

The cost of undertaking a continuing comprehensive diabetes control program is not excessive. It is believed that the cost will be lowest and the success greatest where the cooperation is closest between medical society, local health agencies, and the community.

From the public health point of view, prevention is the most important aspect of the problem. In diabetes preventive measures which lend themselves to practical application by the public are provided by our knowledge of the common factor of hereditary susceptibility, the high incidence of obesity often found as a forerunner, and the frequency with which acute infection or exacerbation of chronic infection "lights up" the pathologic process.

Even though the exact causative agent or the specific host factor responsible for diabetes is not known, early detection is a preventive measure and it is practical on a community-wide basis.

It is believed that relatively simple screening tests will find most of those individuals in the population who are most likely to have undetected mild or early diabetes. Examination of both blood and urine for sugar between one and two hours postprandially will result in the most efficient detection of mild diabetics. Either blood analysis or urinalysis alone will yield a significant number of unknown diabetics, although evidence to date points to the greater efficiency of blood sugar screening in detection programs.

The ideal detection center is in the private physician's office. It is unfortunate, however, that the average individual does not go to his physician until signs and symptoms of disease have existed long enough to produce discomfort or pain. Methods used in mass chest x-ray studies have demonstrated beyond doubt the important part public health can play in uncovering early, asymptomatic cases of disease at a stage most amenable to successful treatment. The practicality and advisability of public health departments and organized community efforts supplementing the efforts of private physicians in mass diabetes detection programs can hardly be doubted.

There is knowledge available which the diabetic patient should acquire in order to cooperate in the control of his condition. This should be presented in a manner conducive to the satisfactory mental and physical adjustments to a restricted regime which must be made.

It is apparent then, that the present state of medical and health knowledge permits an active community program in diabetes control. Therefore, it is believed that the first requirement for a practical public health program must be a sincere cooperative understanding and working agreement between private physicians (the medical society), public health officials, and representatives of the organized community. Then the functions of the health department in the control of diabetes may properly be:

1. Detection of new cases of diabetes by screening large groups of the population with urine and blood tests for sugar. A case finding program should be continually pursued. Of great importance is the prompt referral to their private physicians of diabetes suspects with follow-up to see that the cases understand the importance of obtaining medical supervision and care.

2. Supplementation when needed in the education of the diabetic patient concerning the basic principles of diabetes therapy in order that he may cooperate fully with his physician in the complete control of his condition.

3. Education of the general public concerning the early symptoms of the disease so that the person with incipient diabetes will seek advice from his physician early in the course of his illness.

The principles of a cooperative public health program in diabetes control were agreed upon by the American Diabetes Association and the Diabetes Branch of the Public Health Service in 1946. The primary objective outlined was to seek prevention of illness and disability through education and early detection.[8] With reference to planning preventive measures, Dr. Russell M. Wilder says:

> The importance of early detection of diabetes cannot be overemphasized. Treatment now is usually postponed beyond the time when such restoration of pancreatic island functions can be expected. Intensive management of diabetes offers greatest promise when it can be instituted at the very onset of the disease. However, this involves detecting the disease on its incipience, which rarely has been possible. For this reason all health examinations should include some screening tests for diabetes with a careful follow-up of the diabetic suspects they disclose. An examination such as this made every year in all schools, colleges, and other institutions, also in all business firms and factories, would contribute greatly to the public health. For this reason also, the present active interest of the United States Public Health Service in undertaking diabetic surveys of communities as in Oxford, Massachusetts, and in Jacksonville, Florida, should receive all possible support from practitioners of medicine and specialists in diabetes.[9]

There is experimental and clinical evidence to demonstrate the value of early diagnosis of diabetes. The generally accepted theory of the pathologic processes is that there is insufficient production of insulin resulting from a decreased functional capacity of the islands of Langerhans or an increased inhibition of the action of insulin in the body. Investigators have provided evidence in experimental animals that the pancreatic islet cells have a capacity for regeneration.[10-12] In diabetes, the pathologic changes in the pancreas are reversible if corrective measures are taken early enough. Before the discovery of insulin it was the severe diabetic who showed the serious complications of the disease—acidosis and diabetic coma—from which more than half of the cases died. Today, the long duration case of diabetes is prone to develop arteriosclerotic and other degenerative complications prematurely. The mild, undetected diabetic is usually overweight and uninformed. He is prone to develop prematurely the vascular pathology which may produce arteriosclerotic changes leading to invalidism.

The Oxford, Massachusetts, survey of a general population group revealed that early case finding of diabetes could be achieved on a mass basis.[3] Table 1 shows the comparison of the value of case-finding efforts in a general population group such as Oxford, Massachusetts, with a similar study using the same diagnostic procedures in bleod relatives of known diabetics in Jacksonville, Florida. The testing of 753 relatives brought to light 31 previously unknown diabetics, but it required the testing of 3,516 people in a general population group to yield approximately the same number of new cases. You will note that 30 new diabetics were discovered from a group of 558 relatives between the ages of fifteen and seventy-four

TABLE 1.—Results of Diabetes Testing Program Among General Population in Oxford, Massachusetts, and Among Relatives of Diabetics in Jacksonville, Florida

	Oxford, Mass. General Population			Jacksonville, Fla. Relatives of Diabetics

United States, 1945	25.2	17.0	16.1	11.0	11.8	8.7	5.0	2.2	100.0

years. This is 5.4 per cent of new cases detected in a study of blood relatives of diabetics as compared with approximately 1 per cent in a general population group of 2,514 people in the same age group in Oxford, Massachusetts. The table shows for the testing of relatives that the number of diabetics in the age groups fifteen to forty-four is 3.2 per cent and from forty-five to seventy-four years it is 10.8 per cent. In the general population group these percentages for the same age groups were 0.3 and 2.2 per cent, respectively. No new cases were observed under fifteen years of age in either study. It is noted that out of 69 people over seventy-five years of age in Oxford, five persons, or about 7.2 per cent, were discovered as diabetic in comparison with one case out of three among relatives of the same age group in Jacksonville, Florida. The latter figures here are, of course, too small for reliable comparison.

In the comparison of percentage age distribution of the two groups in Table 2, you will note that the relatives tested in Jacksonville comprise a somewhat younger group than that of the general population of the United States. In the Oxford studies the age distribution much more closely approached the national census figures. Although not shown in the tables, it is noteworthy that in Oxford it was found that the disease was almost as prevalent among men as among women, even more prevalent among men in the newly discovered diabetics, that is, 1.0 per cent as compared with 0.8 per cent, respectively.

Because diabetes found in an early stage is much easier to control, it seems worth while to continue studies with younger age groups in an attempt to define the prediabetic or potential diabetic state, particularly in children and young adults.

It is noteworthy to comment on the preliminary results of one particular case-finding effort in the general population in Brookline, Massachusetts. This was incidental to, but ran concurrently with, a tuberculosis case finding program. Out of approximately 6,000 adults who responded for chest x-rays ten new active cases of tuberculosis were discovered, a rate of 0.17 per cent. At the same time that the people were having their x-rays, the diabetes demonstration unit offered tests of urine and blood for sugar, and 2,100 of the 6,000 were given these tests. Of this number, 18 new diabetics were discovered, or about 0.88 per cent (five times the discovery rate of tuberculosis). It is of interest that in this same community in 1947 there were three reported deaths from tuberculosis and 25 reported deaths from diabetes mellitus.

In all of the diabetes detection work in which assistance is given by the Public Health Service, every newly discovered or suspected case is referred promptly to the family physician for further study, diagnosis, and treatment. Cases with an abnormal finding on first examination are rechecked for confirmation before referral. All confirmed abnormal laboratory findings are sent directly to the private physician designated by the person examined. A general statement indicating whether the tests are "normal" or whether further study is needed is mailed to each person examined.

The operation of that part of the public health program which includes the education of the patient and his family has been very gratifying. There probably is no other disease in which the education of the patient plays a more important role in producing mental and physical adjustment, happiness, and successful treatment than in diabetes. Regular medical supervision is necessary, but the patient must carry out his own treatment from day to day, and the progress of his case depends to a great extent upon the manner in which he takes care of himself. Beyond any doubt, the most logical and best person to give the diabetic patient the necessary instruction for living intelligently with his diabetes is the private physician, either personally or with the assistance of his nurse and dietitian.

Unfortunately, not many physicians have the time or the funds to provide such facilities. Dr. Warvel of Indianapolis says, "We are quite convinced that very little can be learned by routine office calls by the diabetic to the physician's office unless he has had previous hospitalization. Few doctors have time to spend an hour or more at each office visit with these patients to teach them the basic principles of their disease."[13]

There seems to be little doubt in the minds of diabetes specialists that the well-informed diabetic patient has fewer complications, is more cooperative and happier, and usually lives longer. On this premise a school or instruction class for

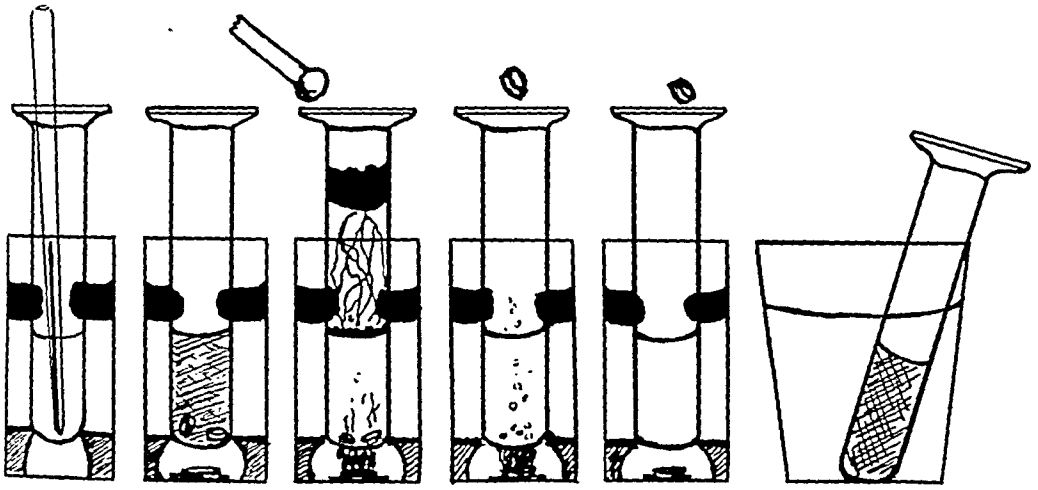
diabetics was organized over a year ago in Jacksonville, Florida. An advisory committee from the county medical society assisted the staff of the diabetes demonstration unit in planning the details of instruction. During the first year 324 persons attended the classes, 70 of whom were friends or relatives of diabetics.

In Table 3, a preliminary analysis of the class attendance records in the school for diabetics in Florida reveals that 123 patients have been referred to the instruction class by the diabetes clinic of the county hospital. Of these, 34 were white, and 89 were Negro. You will note that 121 patients, of whom 93 were white and 28 Negro, were referred to this class of instruction by private physicians. Forty-seven different physicians within Duval County and three physicians outside the immediate area made these 121 referrals. Many physicians have expressed their appreciation of this facility, saying it has proved of practical benefit to them and their patients. They have found that education by this medium results in a more cooperative, happier, and better controlled patient and one who is more regular in returning to his doctor for check-ups. The instruction in this school for diabetics is given by the professional members of the diabetes demonstration unit in Jacksonville. This unit is composed of a medical officer, a public health nurse, a nutritionist, and two technicians, all specially trained in diabetes work. The advisory committee from the local medical society works closely with this group, advising and consulting, as well as reviewing the methods and contents of the instruction classes. A series of six two-hour classes are given. Special night classes have been added at the request of those who are unable to attend during the day.

To further the education of the patient a monthly newsletter is compiled through the efforts of the medical director of the diabetes unit, his professional staff, and the medical advisory committee. This letter is sent to all diabetics and their relatives who are interested in receiving current information about diabetes.



The diabetes demonstration control units in Brookline, Massachusetts, and Jacksonville, Florida, function as a part of the local health departments. Voluntary health agencies such as the visiting nurses association are assisting to a great extent with the program. Every phase is developed with the advice, consultation, and close cooperation of the medical advisory committee from the local medical society. In Brookline, Massachusetts, a lay advisory committee assists the health department and the medical advisory committee in the promotion and planning of the program.

In the epidemiologic phase of the program, analyses of data are being carried out in order to learn more about the behavior of diabetes in the general population as compared with the characteristics it usually shows among clinical or hospital groups.

Many of the research objectives in diabetes are being administered through another division of the Public Health Service. Among other diseases of metabolism and endocrinology, diabetes is one of the important fields of research assisted through grants-in-aid recommended by the Metabolism and Endocrinology Study Section of the Division of Research Grants and Fellowships of the National Institutes of Health.

A "meal planning" booklet is being developed through the cooperation of the Education Committee of the American Diabetes Association, the American Dietetic Association, and the Diabetes Section of the Public Health Service. This booklet will give the consensus of experts on the basic food values and how to use them in planning meals for the diabetic.

One very important objective of our diabetes program is the development of simplified detection and screening procedures. A cheap, quick, and simple screening method for determining blood glucose has been introduced.[14] Rough drawings of the equipment and procedure appear in Fig. 1. By this method it is concluded in five minutes whether a blood sugar is above or below a predetermined screening level. You will note the procedure is carried out by filling a test tube with tap water to the 5 ml. mark; 0.1 ml. of capillary blood from the finger tip or ear lobe is collected by means of a capillary pipette and added to the tap water. Tablet I, containing zinc sulfate and sodium chloride, and tablet II, containing potassium iodide and sodium bicarbonate, are added to the solution which is boiled by lighting methenamine heating tablets as shown in the diagram. The blood proteins are coagulated by the zinc hydroxide formed, and, as the solution boils, the cake of protein is pushed upward in the test tube by the steam. This protein cake can be removed with the glass scoop when it reaches the funnel-shaped mouth, obviating the necessity for filtering.

1. 0.1 ml. of blood is introduced into 5 cc. of tap water.
2. Tablet 1 ($ZnSO_4$,NaCl) and Tablet 2 (KI,$NaHCO_3$) added to the solution of blood and water.
3. Heating tablet lighted, blood proteins coagulated forming a cake, caked protein pushed to the flared mouth of the tube, protein removed with scoop.
4. Tablet 3 ($K_3[Fe(CN)_6]$, Na_2CO_3, Starch, NaCl) added to the deproteinized solution, another heating tablet added and lighted.
5. Tablet 4 (tartaric acid, $ZnSO_4 \cdot 7H_2O$, Starch) added to the cooling solution.
6. Tube immersed in a container of cold water.

FIG. 1. Diagram of simplified detection and screening procedure.

Then tablet 3, containing potassium ferricyanide, sodium chloride, and starch, is added and the solution boiled again. At the end of the second heating period tablet 4, containing tartaric acid, zinc sulfate, and starch, is added, and the test tube is immersed immediately in cold water. When cold the solution will be either blue, due to the formation of the starch iodine complex, or colorless if no iodine is present. In other words, if solution is blue, the blood sugar is below the predetermined level, but, if colorless, it is above and merits further investigation.

In surveys our experience so far indicates that knowledge of the actual blood sugar value is less important in screening work than noting whether or not a certain level is exceeded. While certain technicalities at first prevented the use of the screening test for mass surveys, revisions have been made, and the test is now considered satisfactory for individual or mass screening. The test is useful wherever a quick laboratory screening service is needed and routine standard laboratory facilities are not available. It is particularly applicable to use for screening by the general practitioner or in a small office laboratory. Further work on diagnostic methodology is in progress.

A certain number of false positives will necessarily be encountered owing to the critical screening levels at which the values are set. It is not within the scope of the proposed procedure to replace clinical judgment required to establish a diagnosis. A positive screening test creates a suspicion index and recommends more elaborate study. The screening test does not make a diagnosis.

There is now available a machine, the Hewson Clinitron, which performs this type of screening test at a top capacity of two tests per minute.

Summary

1. A discussion is presented of the reasons why diabetes is believed to constitute a public health problem. A practical program for solution is described as possible through cooperation between physician, health agency, and organized community effort.

2. Blood and urine testing programs among 736 blood relatives of known diabetics in Jacksonville, Florida, have revealed a discovery rate of 5.4 per cent in the age group fifteen to seventy-four years, about five times that obtained in work with a general population group in Oxford, Massachusetts.

3. Many busy practitioners of medicine are using the school for diabetics in the Diabetics Demonstration Unit in Jacksonville, Florida, to provide instruction for their patients who have diabetes. They have found that a thorough understanding of the disease by the patient results in a more cooperative patient who is healthier and happier and who may expect to live longer and have fewer complications.

4. All plans for the diabetes demonstration control units are formulated with the help and advice of a committee of the local medical society. These plans are carried out as a function of the local health department with the cooperation and assistance of voluntary health agencies, such as the visiting nurses association.

5. A quick, new screening method for blood glucose determination, thought to be particularly useful to the general practitioner and for mass surveys, is described and illustrated.

Discussion

I. Jay Brightman, M.D., *Albany.*—This scholarly presentation by Dr. Wilkerson leaves no doubt as to why his name is now so intimately associated with the new movement in the public health field, the control of diabetes. The programs conducted by the United States Public Health Service in Massachusetts and Florida have clearly demonstrated that the welfare of the diabetic patient can best be served by a close partnership between the private physician and the public health agency.

The general pattern of the public health approach to the control of disease is well applicable to diabetes. The last few years have seen the development of the necessary refinements required to fit diabetes upon the public health lathe. The mass survey for diabetes, utilizing the speedier biochemical tests, may now be accepted as a proved case-finding weapon comparable to that applied to tuberculosis. The fact that one third of the patients undergoing routine chest examinations voluntarily submitted to blood and urine tests indicates that the tests for diabetes are not particularly objectional or painful. Possibly with a more intensive educational program, this percentage of volunteers may be significantly increased. From the epidemiologic viewpoint, the investigations made upon the blood relatives of known diabetics, with the resulting fivefold increase in fruitfulness, are particularly significant. The Brookline approach was really rifle-shooting compared to the shotgun approach made in Oxford. The Oxford type of mass survey might be expected to pay increased dividends if conducted among racial and age groups in which the prevalence of diabetes is known to be higher than in the general population.

If the prevalence of diabetes by age group, as found in the Oxford survey, is applied to New York, it may be estimated that there are about 240,000 diabetics in this State, of whom only approximately half have been diagnosed. The diagnosed diabetic, particularly if discovered early, has a good possibility of making a satisfactory adjustment to his disease, of having a normal life expectancy, and of enjoying life with few restrictions. The undiagnosed diabetic should have the same opportunities. We must determine and correct the reason for the condition remaining unknown, whether it be ignorance, neglect, or lack of adequate facilities. Public health education must not only advise the patient with suggestive symptoms to seek examination but must encourage all persons to go through a periodic health check-up so that asymptomatic disease of any type may be detected.

A complete program for diabetes might well include services to assist the private physician in the management of his case. Group courses designed to interpret to the patients the recommendations of their physicians would certainly promote a more careful adherence to dietary and insulin regimes. Such services are well within the province of the bureaus of nutrition of State and local health departments. Teaching days for physicians, two- or three-day refresher courses, and group consultation clinics conducted in the more rural areas by specialists coming from the medical centers would follow closely the type of program already operating for other diseases. The pattern is there; the tools have been refined, the potentialities are great. There remains the question of the funds and, even more important, the qualified personnel necessary to administer such a program.

The number of diabetics in the population is increasing and will continue to increase as the control of this disease improves. H. G. Wells, a diabetic himself, suggested that the excellent training a well-controlled diabetic receives and the excellent discipline to which he subjects himself might well be reflected in his nonmedical activities and that possibly this might be advantageous. Addressing fellow diabetics back in 1935, Mr. Wells stated, "We are a high and austere cult. Our characters are strengthened by a perpetual self-control; we have learned to detest the pasty and saccharine in thought, word, and deed. We shall be plain and fine with each other. Formerly diabetics died, but now I shall begin to look for the diabetic influence in every aspect of life, in art, science, conduct, a new delicate strength, a restraint and a clearness. Am I writing nonsense? Not altogether. For my own part I have certainly found diabetes an invigorating diathesis."

Nonsense or not, the diabetic patient and the world of which he is part are indebted to Dr. Wilkerson and the Diabetes Section of the U.S. Public Health Service for their pioneering work in this field.

GENITOURINARY SYMPTOMS DUE TO EXTRINSIC DISEASE*

WILLIAM J. KENNEDY, M.D., Gloversville, New York

THE differential diagnosis between certain urinary tract lesions and disease of other viscera frequently presents a problem which, in the final analysis, must be solved by the urologist. The kidney and the gastrointestinal tract have a common nerve supply derived from the solar plexus. Thus, it is apparent that renal or ureteral pain may simulate disease of practically any abdominal or pelvic organ, and it is equally apparent that the reverse may also be true.

Referred pain, especially to the back, may be due to disease of almost any intra-abdominal organ or to local causes such as myalgias, strains, postural defects, vertebral lesions, or any inflammatory or mechanical change involving sensory nerve roots. Tubercular spondylitis and the chronic ganglionitis of tabes are capable of producing pain closely simulating that of renal colic.

Motley discusses a pain syndrome closely simulating ureteral colic.[1] It consists of pain arising in the lumbar area and radiating around the flank to the abdomen and downward toward the bladder. The lesions found responsible for this syndrome involved the eleventh and twelfth thoracic and the first lumbar nerve segments. In some of his patients urologic investigation had been done, and treatment based on faulty diagnosis had consisted of nephropexy or the use of some abdominal support based on the assumption that the symptoms were due to ptosis, while another group of patients was subjected to anywhere from five to 100 cystoscopic instrumentations for the correction of supposed ureteral strictures. Motley states that the only result of this treatment has been "persistence of the same pain, a leaner purse and a discouraged outlook on life, and a dim view of the medical profession as a whole."

Orr, Mathers, and Butts have published case records in which pain identical with that of ureterorenal disease was found to be due to fibrolipomatous nodules located at the level of the twelfth dorsal and first and second lumbar vertebrae.[2] In these cases, temporary relief of pain followed injection of novocaine into the nodule and permanent relief was obtained following surgical removal.

Bladder symptoms due to lesions of the female pelvis are extremely common and, as a rule, present no serious diagnostic problems. Tumors, uterine malpositions, and alteration in the normal anatomic relations due to gynecologic surgery or childbirth are the most important factors.

Cystitis of the allergic variety is being reported with increasing frequency, although the small number of case reports in literature would lead one to believe that the condition is rare. It is quite probable that a greater awareness on the part of the urologists will add many more cases to the literature. A factor which militates against more thorough study of the suspected cases may be the transitory duration of symptoms. This is most apt to occur if the allergy is due to food hypersensitiveness. One should suspect an allergic cystitis in any patient presenting transitory symptoms of cystitis who gives a history of having had attacks of urticaria. It was possible to study the following case over a considerable period of time because pork, the only meat in the patient's diet, was eaten almost daily.

Case 1.—C. A., a girl aged five, complained of intense urgency, frequency, dysuria, and nocturia with intermittent attacks of gross hematuria. The past history and general physical examination were negative. Urine examination showed leukocytes and red blood cells. Repeated cultures of the urine were sterile. Guinea pig inoculations were later reported negative. On cystoscopic examination circumscribed areas of varying size were seen on the bladder wall. They appeared slightly elevated. Some had a pale center surrounded by an area of hyperemia and edema, while others had centers which were hemorrhagic in character. The cystoscopic picture resembled no lesion with which I was familiar at that time.

A more careful and detailed history obtained from the child's mother revealed the following facts: The child's parents who lived on a small farm had decided to defeat the then current meat shortage by raising pork for home consumption, so pork had been almost the only meat in the family's diet. Further questioning also revealed that the child had had an occasional attack of hives. Intradermal tests showed marked sensitivity to pork, and elimination of pork from the diet produced rapid recovery from all symptoms. It is noteworthy that this child had never had any previous allergic manifestations, nor has she shown any since.

Ordinarily appendicitis presents no very serious diagnostic problem; yet in a survey of 328 patients operated for appendicitis, Wels and Potter found 12 with sufficient urologic manifestations to make diagnosis difficult.[3] Of the patients studied 25 per cent had suprapubic tenderness; 33 per cent showed right costoverte-

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo, Section on Urology, May 5, 1949.

* Chairman's address.

bral tenderness; 33 per cent showed albuminuria, and in 42 per cent there were red blood cells in the urine. It is significant that in 75 per cent of the cases showing urologic symptoms the appendix was either retrocecal or pelvic. In addition to these symptoms, we have seen several patients in whom the first symptom noted by the patient was pain in the right testicle. Urinary tract symptoms due to appendicitis are easily explained as being due to extension of the inflammatory process to adjacent structure. The following case history illustrates this point.

Case 2.—W. N., a thirty-six-year-old white man, was admitted to Littauer Hospital complaining of pain in the right loin. He stated that for three weeks before admission there had been pain in the right abdomen which at times was colicky in character. It was not referred. It was unaccompanied by vomiting or other digestive symptoms and had not confined the patient either to his bed or indoors. On the day of admission, the pain became much more severe, and he had several severe chills. His past history was not significant except that he had tubercular bone disease in one leg during childhood.

Physical examination showed a rather poorly nourished man whose temperature was 102.8 F. The head and neck, respiratory, and circulatory systems were negative. The right side of the abdomen was slightly rigid, and in the right upper quadrant an indefinite mass was palpable. There was marked tenderness at the right costovertebral angle. On the right thigh were two linear scars resulting from bone tuberculosis suffered in childhood. Neurologic examination was negative. The hemoglobin was 90 per cent, and the red cells 4,365,000; white cells varied from 12,800 to 16,600. Polymorphonuclears showed 80 per cent top level. Blood urea nitrogen was 24 and blood sugar 108. At cystoscopy, the bladder presented nothing of interest. Urine obtained from the bladder and both kidneys was sterile on culture and negative for tuberculosis on smear and guinea pig inoculations. Pyelogram showed the right kidney fixed as demonstrated by double exposure films taken at inspiration and expiration. The shadow of the right psoas muscle was obliterated. There was bowing of the spine, and the right ureter was displaced laterally. Both kidneys showed satisfactory elimination of pthalein.

Diagnosis of perinephritic abscess was made, and at operation a large perinephritic abscess was opened and drained through the usual loin incision, finger dissection being used after the perirenal space was entered. The pus evacuated from the abscess had a strong fecal odor suggestive of Bacterium coli infection, and on culture staphylococcus and B. coli were isolated.

The patient reacted satisfactorily, and on the following day his temperature, which had ranged between 103 and 104.2 F., dropped to normal and, except for an elevation to 100.4 F. which occurred on two occasions, remained normal. On the third postoperative day it was noticed upon dressing the wound that the drainage, which until now had been purulent, was now definitely fecal and remained so during his entire stay in the hospital. He was discharged three weeks after operation with the wound healed except for a small sinus which drained a small amount of fecal material at irregular intervals. It was felt that this would heal spontaneously.

Six months later, the sinus had not healed, and the patient was readmitted to the general surgery service. An x-ray of the colon by means of barium enema showed the colon filling only to the hepatic flexure and the colon at this point appeared markedly irregular at its upper surface. At operation through a right rectus incision, it was found that no ascending colon was present. There was evidence of an old appendiceal abscess. The infected portion of the colon was removed, and an anastomosis of the ilium and transverse colon was done. Patient made a rather smooth postoperative recovery.

In this case, we have a frank urologic lesion due to direct extension from the appendix. The true nature of the lesion was not suspected until fecal drainage occurred, although the presence of B. coli in a perinephritic abscess should have aroused our suspicions. The entire picture was made more obscure by the congenital malformation of the intestinal tract and the unusual site of the appendix.

Pressure on the ureter by pelvic tumors and cysts, enlarged iliac lymph nodes, as reported by Marshall and Schnittman; Hodgkin's disease; and aneurysms of the iliac or abdominal aorta may produce symptoms which are indistinguishable from obstructive lesions due to intrinsic factors.[4] The following case belongs in this category.

Case 3.—W. M., a sixty-eight-year-old man, was admitted to the Littauer Hospital for urologic investigation. During the night before admission, the patient was awakened by pain in the right testicle. Pain was constant and severe enough to produce a slight degree of shock, but a physician was not called until the following morning. Morphine gave prompt relief. Examination by his physician elicited tenderness in the right costovertebral angle. Urine showed many red blood cells in the uncentrifuged specimen. An admission diagnosis of renal colic due to calculus was made. The relief of pain by the use of morphine was so complete that the patient came to the hospital in a taxicab and walked in unassisted.

When the patient was examined at the hospital, his pupils were equal and reacted normally. The lungs were clear. There was a loud systolic murmur heard over the entire precordia, the second aortic sound being greater than the second pulmonic. The abdomen was slightly distended, particularly in the epigastrium. There was some tenderness on pressure in the right upper quadrant and marked tenderness over the right costovertebral angle. Neither kidney was palpable. The right inguinal ring was patent, but there was no evidence of extrusion of the bowel or omentum. The scrotal

contents and prostate were normal. Neurologic examination was negative.

At cystoscopy, the passage of the instrument caused very profuse bleeding from the anterior urethra where some obstruction was encountered. The bladder contents were clear, and the bladder mucosa appeared normal. Both ureteral orifices were normal in appearance, and clear urine was emitted from each ureter. Number 6 catheters were passed easily. No obstruction was encountered. Flow from the catheters was normal in rate and rhythm. Flat film was negative for evidence of stone. The pyelogram showed both pelves normal in size and contour. Examination of urine obtained at cystoscopy showed the bladder urine to be filled with red blood cells. There was an occasional coarse granular cast. Urine from the right kidney showed only an occasional fine granular cast and from the left kidney 10 to 15 epithelial cells and an occasional red blood cell per high power field. Urine cultures were sterile.

When x-ray studies had been completed, the catheters were removed and the panendoscope introduced in order to identify the lesion producing the obstruction and urethral hemorrhage. In the posterior portion of the anterior urethra an hemangioma was found situated on the floor and left lateral wall of the urethra. This undoubtedly was the source of the red blood cells found in the urine. The patient's blood urea ranged between 30 and 61. Hemoglobin was 85 to 60, red cells from 3,950,000 to 3,140,000, white cells from 19,000 to 10,600, polymorphonuclears ranged from 93 to 76 per cent. Sedimentation rate was 64. Intravenous fluids and several transfusions produced only temporary improvement.

The patient expired rather suddenly after complaining of severe abdominal pain. At autopsy, an aneurysm of the abdominal aorta, situated just above the bifurcation, was found to have ruptured. In retrospect, re-examination of the pyelogram showed the right kidney and ureter to be situated slightly more laterally than the left. However, this deviation was not beyond normal limits.

Hematuria is one of the most important and certainly one of the most dramatic symptoms of disease of the urinary tract. In the review of 3,800 cases with urologic disease, MacKenzie reported 21.6 per cent had hematuria.[5] In 150 cases of surgical disease of the kidney, Herman found hematuria present in 43.3 per cent, while only 3.9 per cent of the general admissions to the Pennsylvania General Hospital gave a history of hematuria.[6] We must conclude from this that while hematuria is a prominent and frequent symptom in urologic practice, it is a comparatively rare symptom in general practice. It has been shown from various surveys that the incidence of hematuria due to extrinsic disease is approximately 5 per cent.

Routine urologic investigation will usually disclose the local causes of hematuria, but in those cases in which the hematuria is due to extrinsic disease the problem may become extremely difficult. Of the many common general causes of hematuria the various blood dyscrasias are of prime importance. Primary anemia, polycyphemia, and leukemia ordinarily will present no very great difficulty. Appropriate laboratory tests will confirm the diagnosis of occult jaundice, while the family and personal history will furnish the necessary clues if hemophilia is the causative factor. In those cases due to purpura, the characteristic hemorrhagic skin lesions will render the diagnosis easy. In Hodgkin's disease, however, the diagnosis may be much more obscure and final confirmation may depend on bone marrow studies or pathologic section of the lymph glands. Infectious fevers, namely, malaria, typhoid, and scarlet fever are of little importance to the urologist, since the diagnosis is usually clear.

Hematuria due to medicinal or other chemical factors is perhaps more common than generally supposed. Of the numerous drugs which may cause hematuria, the sulfonamides undoubtedly head the list. The role of urotropin and turpentine has long been recognized. Lyons reported six cases of hematuria in workmen employed in the aniline dye industry.[7]

The habitual use of aspirin for the treatment of headache was found to be the cause of rather profuse hematuria in two women referred to me for urologic investigation.

Summary

1. The upper urinary tract and the gastrointestinal tract have a common nerve supply.

2. Disease involving intraperitoneal viscera may simulate lesions of the urinary tract.

3. The differential diagnosis usually becomes the problem of the urologist.

4. Abstracted histories of illustrative cases are presented.

RELATIVE IMPORTANCE OF LEADING CAUSES OF DEATH IN NEW YORK CITY

GODIAS J. DROLET, New York City

(From the New York Tuberculosis and Health Association)

THE steadily declining mortality from tuberculosis, although more new cases have been reported lately, has naturally lowered the rank of the "white plague" among leading causes of death.[1] Several keen observers—Dempsey of the National Tuberculosis Association, Dickinson of the American Medical Association, Edwards of New York, and Stocks of England—have pointed out that a closer look into the age at which deaths occur from the more important killing diseases or conditions necessitates a rearrangement of the list if the relative importance of the principal causes of mortality is to be appreciated fully.[2–5]

Edwards, when discussing the importance of the leading causes of death for the entire United States during the year 1947, recalled that, according to ordinary numerical listing, tuberculosis among both males and females ranked only seventh that year among the chief causes of death. But he carefully added that if one considered the age at which the deaths from various causes occurred during the working period of life, primarily between fifteen and sixty-five years, men dying from tuberculosis at an average age of forty-eight and eight-tenths years lost sixteen and two-tenths years, and the disease rose to third place among leading causes of death. Moreover, in the case of the deaths from this same cause in the female sex, since they died at the age of forty and four-tenths years on an average, they lost even more, namely twenty-four and six-tenths years of the working period previously mentioned. From being seventh on the list, tuberculosis mortality among women, therefore, rose to first place among the leading causes of death in being responsible for loss of future working lifetime.

Stocks, chief medical statistician of the General Register Office in London, when studying tuberculosis mortality in England and Wales in 1945 in comparison to certain leading causes of death, which in this instance were syphilis, cancer, and fatal accidents, remarked that "on the average a death from tuberculosis robs the community of twenty-four years of future working life between the ages of fifteen and sixty-five, whereas a cancer death causes a loss of only five years between those ages, and a fatal accident eighteen years ..... This suffices," he added, "to establish the statement that tuberculosis is our number one problem, in that its eradication would confer more benefit to the community than would be the case for any other disease."

In New York City, during 1948, a total of 81,651 deaths from all causes occurred. The great majority of them, 88 per cent, were due to the following seven groups of diseases or conditions: first, came those due to cardiovascular renal diseases, a total of 39,444; second, cancer with 15,169 deaths; third, fatal accidents, 3,813; fourth, deaths associated with diabetes, 3,736; fifth, the group of deaths due to diseases of infancy or congenital malformation in the newborn, 3,436; sixth, tuberculosis, 3,112; and seventh, pneumonias, 3,037.

However, mortality was not evenly divided or due to identical causes, at least as to frequency, in each sex. While in both the male and female sex heart diseases and cancer were the first two leading causes of death, among men accidents were third, and among women, diabetes. In the male sex, tuberculosis was fourth among leading causes of death, followed in fifth place by pneumonias and in sixth place by cerebral hemorrhage, then diabetes and nephritis. In the female sex in New York City, the fourth principal cause of death in 1948 was cerebral hemorrhage followed by accidents, nephritis, pneumonias, and tuberculosis.

In a mere numerical listing of causes of death tuberculosis was, therefore, fourth in the male sex and only eighth in rank in the female sex. But this is rather an inadequate observation, for, if we look beyond that point and see at what time of life tuberculosis or the other causes strike, we have a much more enlightening view of what really takes place. Among men in New York City dying from some form of heart disease during 1948, the average age was sixty-four and nine-tenths years. The deaths associated with diabetes or due to cerebral hemorrhage occurred even later; the first struck down at an average of sixty-five and three-tenths years, and, the second, at sixty-six and three-tenths. Both the deaths from nephritis or from cancer among men occurred at an average age of sixty-two. Accidents, however, took toll at an earlier age, on an average of fifty-two years. The pneumonias

Presented at a meeting of the Tuberculosis Committee of the New York Tuberculosis and Health Association, New York City, November 10, 1949.

TABLE 1.—Loss of Future Working Lifetime (18 to 65 Years) Due to Principal Causes of Death, New York City for the Year 1948*

Rank	Cause of Death	Number of Deaths	Average Age at Death (Years)	Person-years Lost for Each Death		Total Person-years of Working Life Lost		Economic Loss to Community†
			Males					
					Rank		Rank	
1	Heart diseases	18,203	64.9	0.1	(6)	2,667	(6)	$ 8,001,000

5	Accidents	1,403	62.7	2.3	(4)	3,240	(4)	6,480,000
6	Nephritis	1,211	63.4	1.5	(5)	1,827	(5)	3,654,000
7	Pneumonias	1,104	53.2	11.8	(2)	13,072	(3)	26,144,000
8	Tuberculosis	910	38.7	26.3	(1)	23,938	(2)	47,876,000

* Based on reports by courtesy of Bureau of Records and Statistics, Department of Health, City of New York.
† Department of Labor, State of New York—Weekly earnings, workers in manufacturing industries, 1948, New York City: men $67.22 to $72.44; women $42.83 to $46.18. Average annually: men $3,640; women $2,312. Computed, on basis of $3,000 annually for men and $2,000 for women to allow for unemployment, by G. J. Drolet, New York Tuberculosis and Health Association.

were responsible for death among men mostly of fifty-one years. Deaths from tuberculosis occurred at the earliest age in any of those causes listed here, fifty and six-tenths years.

Among women, in general, the average age at death was higher except in case of cancer and especially of tuberculosis (Table 1).*

Productive Work Period

If we consider that working lifetime in New York City for most people is between the ages of eighteen† and sixty-five, we find that among men the deaths from the causes listed were responsible in each case for the loss of the following person-years: heart disease only one-tenth of a year; both the deaths from cerebral hemorrhage and those associated with diabetes, since they occur on an average after age sixty-five, no loss, comparatively speaking, of working lifetime; in the case of cancer, about two and one-half years; the deaths from nephritis, a loss of nearly three years. The deaths from accidents, occurring as they do around age fifty-two, were responsible in each instance for the loss of thirteen person-years of working lifetime and those from pneumonias, thirteen and nine-tenths years. But those due to tuberculosis among men, occurring as they did at an age slightly over fifty, on an average, were responsible for a loss of no less than fourteen and four-tenths years of future working lifetime.

Thus, we see that, although on the ordinary listing of the number of deaths tuberculosis ranked fourth as a leading cause, in the case of deaths from this cause in the male sex, on the serious basis of the person-years lost for each death of possible future working lifetime, it ranked first, heart disease being relegated to sixth place and cancer to fifth place.

In the female sex, the deaths occurring in New York City during 1948 from tuberculosis numbered 910 and would seem to be only eighth in numerical rank among leading causes of death. But here again, if we look more carefully into the significance of the deaths from various causes among women, we see that the average age at death among those dying from heart disease was nearly seventy years; the deaths from both diabetes and cerebral hemorrhage were past sixty-five years of age; even those due to cancer were at an average age of sixty-one, and the deaths from pneumonia were at the age of fifty-three.

Deaths due to tuberculosis, however, were at a comparatively earlier period of life, the average age being only thirty-eight and seven-tenths years. Therefore, on the basis of person-years lost for each death during possible working lifetime, namely, from eighteen to sixty-five, those due to heart diseases, diabetes, and cerebral hemorrhage involved no loss since they all occurred after age sixty-five; those from nephritis caused a loss of only one and one-half years from a possible working capacity; those from accidents entailed a loss of two and three-tenths years; those from cancer cut off nearly four years, and the deaths from pneumonia approximately

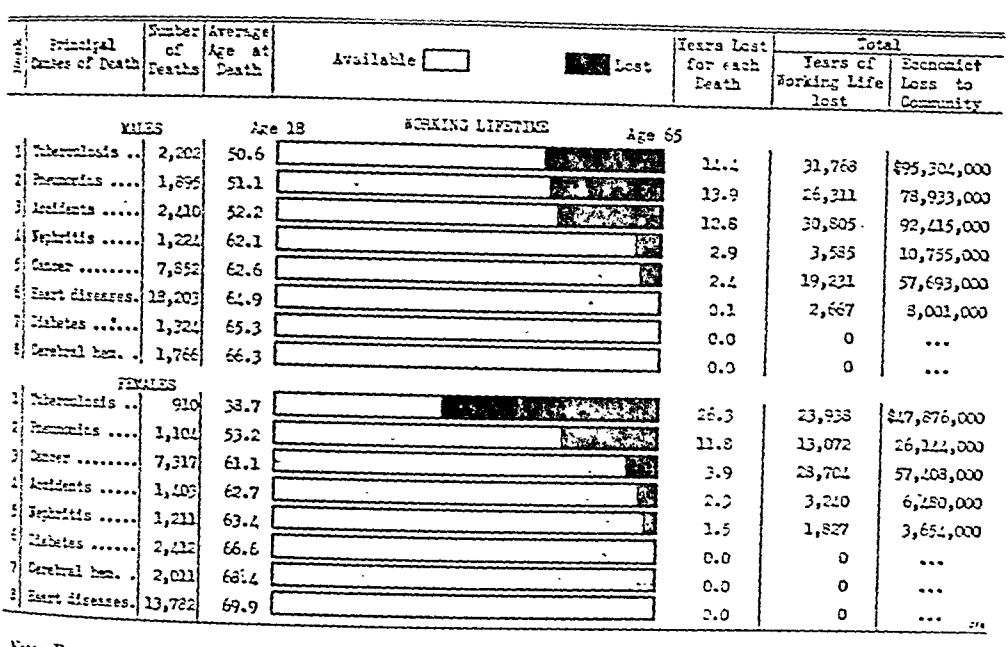
* Average age at death from all causes: women, sixty-one and one-tenth years; men, fifty-eight and two-tenths.
† Younger children must either remain at school or be under vocational training in New York, and, if between sixteen and eighteen, "working papers" from the Health Department are required.

twelve years. Hence, deaths from tuberculosis among women in New York City in 1948 involved a loss of possible future working lifetime of no less than twenty-six years, or more than half the entire working period. On this practical basis of gauging the importance of leading causes of death in the female sex in New York City, tuberculosis now ranks first; pneumonias, second; and cancer, third. Heart diseases, on the contrary, from being first in a numerical listing drop all the way down to eighth place when one considers their relative importance.

Ultimate Total Loss of Working Life

The above comments relating to the age at death do not take into consideration the different number of deaths from the various causes. If, however, we do so now in conjunction with the years of life lost for each death during the working period from eighteen to sixty-five, we find that the deaths from diseases of the heart among men —which totaled 18,203 in New York City in 1948 and where there was involved, because of the average age of sixty-four and nine-tenths, only one-tenth of a year lost for each death— meant a total loss ultimately of 2,667 years of working life. But, on the other hand, in the case of the 2,202 deaths from tuberculosis in the male sex, which occurred on an average at age fifty-one and involved, therefore, in each instance a loss of fourteen years of possible working lifetime, we see a total of 31,768 years of working lifetime lost, the greatest number of any due to leading causes of death among men in New York City.

While tuberculosis ranks first among females according to the loss of working lifetime, since the deaths among women occur at an average age of 38.7 years with a loss, therefore, of 26.3 years, the small number of deaths (910 in 1948) shows a possible total loss of 23,938 years of working life, which is second to the 28,704 years due to cancer, since the deaths due to malignant tumors in the female sex were eight times as numerous as those due to tuberculosis.



Economic Loss Due to Premature Deaths

The world-wide discussion of the influence of economic conditions on daily life has brought home that the everyday business dealings between different nations are bound up in problems of production, distribution, and payment of goods. In particular, it has been shown that the solution lay, especially for those countries that have been dependent upon American aid, in a greater capacity on their part to produce and, therefore, to make goods for exchange available. But production of goods is basically dependent on human labor, and we can understand all the better the importance of a disease on workers if we consider them for what they really are—the most valuable economic units.

On that basis an interesting and revealing computation can be made, for just the twelve-month period of 1948, of what the deaths from the leading causes we have been discussing have meant to the community. And it is there that we see a quite different and truer picture from that suggested by the ordinary listing of causes of death on a mere numerical basis. It is readily possible in this city to estimate fairly accurately the earning capacity of employed people and who, in these days, is not busy either at the shop, office or home (Fig. 1).

The New York State Department of Labor, for instance, for the year 1948 makes available for New York City separately the average annual earnings of workers in manufacturing industries both for men and women. It is sufficient to recall the rather large number of persons employed in the garment and textile industry in New York City or in printing establishments to see that the figures made available by the State of New York are a proper basis for the computation to follow. The Labor Department points out that during 1948 the average annual earnings of men in manufacturing industry was $3,640, and of women, $2,312. If, for purposes of discussion here, we set the possible economic loss from each death among people during their working period at lower figures, namely, $3,000 for men and $2,000 for women to allow for possible unemployment, we have a fair basis for gauging the situation from an economic viewpoint. On that score we see, for instance, that since the deaths among men last year from heart diseases involved a total number of 2,667 years of working life, the economic loss to the community from the cutting off of these workers must at least be approximately $8,000,000, with none whatever in the case of the deaths from heart diseases for the female sex since these occurred at an average age of sixty-nine and nine-tenths.

In the case of tuberculosis, which ranks first in the number of years of working lifetime lost (fourteen years) and where, therefore, among the 2,202 such deaths in the male sex a total of 31,768 years of working life was incurred, we see there a possible economic loss to the community of $95,000,000, the highest from any single cause of death. Even though among women the more numerous deaths from cancer at an average of sixty-one years involve a possible economic loss of $57,408,000, still we find in tuberculosis with its 910 deaths and the cutting off of twenty-six years in each case that there is an economic loss of $47,000,000. In fact, between the two groups of men and women, the deaths of valuable producers in just one year involve an ultimate economic loss

Note: Department of Labor, State of New York: Average annual earnings, workers, manufacturing industries—men $3,641, women, $2,312.
† Economic loss computed above on basis of $3,000 annually for men and $2,000 for women to allow for unemployment.
Based on reports by courtesy of Bureau of Records and Statistics, Department of Health, City of New York. G. J. Drolet, New York Tuberculosis and Health Association.

FIG. 1. Relative importance of leading causes of death according to loss of working lifetime between 18 and 65 years of age (among those dying during 1948 in New York City).

to the community of over $143,000,000. Let us bear in mind that these figures are arrived at on the basis of wages paid, and yet it is obvious that to their employers these workers must have been profitable and, therefore, that as economic units the amounts quoted are conservative and probably an understatement.

Summary

The ordinary numerical listing of leading causes of death is an incomplete statement of the loss from them incurred by the community.

The average age at death from various causes and the years lost during possible working lifetime in New York City during 1948 being taken into consideration, the deaths from heart diseases among men involved the loss on an average of one-tenth of one year for each death: those from cancer, two and four-tenths years; from nephritis, two and nine-tenths years; from accidents, twelve and eight-tenths years; from pneumonias, thirteen and nine-tenths years; and, from tuberculosis, the greatest of any, fourteen and four-tenths years. The latter, therefore, ranked first in importance as a man killer during the most productive period of life.

Among women, the loss of possible working lifetime was least from deaths due to nephritis, (one and five-tenths years) and again greatest from those due to tuberculosis (twenty-six and three-tenths years).

On the basis of years of working life lost and the assigned values or average wages earned during 1948, there was involved in the case of tuberculosis an estimated economic loss among men dying from that disease of $95,304,000 and among women $47,876,000—not to mention that, because of prolonged illness, especially from that disease, there is usually an additional amount of lost earnings prior to death.

According to loss of working lifetime, tuberculosis in New York City is in the first rank of significance among leading causes of death.

twelve years. Hence, deaths from tuberculosis among women in New York City in 1948 involved a loss of possible future working lifetime of no less than twenty-six years, or more than half the entire working period. On this practical basis of gauging the importance of leading causes of death in the female sex in New York City, tuberculosis now ranks first; pneumonias, second; and cancer, third. Heart diseases, on the contrary, from being first in a numerical listing drop all the way down to eighth place when one considers their relative importance.

Ultimate Total Loss of Working Life

The above comments relating to the age at death do not take into consideration the different number of deaths from the various causes. If, however, we do so now in conjunction with the years of life lost for each death during the working period from eighteen to sixty-five, we find that the deaths from diseases of the heart among men —which totaled 18,203 in New York City in 1948 and where there was involved, because of the average age of sixty-four and nine-tenths, only one-tenth of a year lost for each death— meant a total loss ultimately of 2,667 years of working life. In fact, between the two groups of men and women, the deaths of valuable producers in just one year involve an ultimate economic loss

and their physical well-being. The Committee is deeply concerned about the present unsatisfactory state and has given thought to possible remedies.

The discrepancy between the number of medical graduates available and the large number of approved internships is too great to be easily and completely reconciled. It is the opinion of the Committee that the introduction of a two-year internship in all those hospitals with sufficient clinical facilities to warrant them would aid a great deal in partially closing the gap. Such a plan would provide for the preparation of men for general practice or for training in a specialty.

At present, many hospitals have a one-year rotating internship, which is generally not considered adequate in New York City. The Committee believes that a good general internship could be arranged if it continued for two years. One year could be devoted to medicine and its specialties and one year to surgery and its specialties. Such a plan would prove very satisfactory for the preparation of general practitioners. For those desiring to prepare themselves for the practice of a specialty, the internship might be arranged in such a way that the second year would be devoted to the chosen specialty, having the necessity of an extra year of hospital training. This arrangement may permit the second year to be classed as an assistant residency.

In the accompanying diagram the Committee has illustrated the reduction in the number of annual appointments to the intern staff which may be effected with a two-year internship (Fig. 1). It will be seen in diagram 2 that by cutting the number of internships in half the resident structure would be rather top heavy, and there would only be two candidates a year available to go into the specialties. Of course, all this assumes that the total number of house staff which the hospital requires under the present one-year internship is the minimal requirement with respect to personnel. In the diagram we have used the hypothetical case of a hospital which has a house staff of 46, but we feel sure that the same thing would be true, regardless of the size of the house staff.

In diagrams 3 and 4, we have indicated our ideas of the possibilities if a two-year internship were instituted and the number of interns appointed each year cut down to two thirds of the number required under the one-year internship plan. In diagram 4, which suggests the plan of adding another year to the residency, half the interns would be available to go into the specialties.

It is evident that diagrams 3 and 4 offer the most satisfactory arrangement. Only two thirds as many men will be required annually as at present. This will permit a more equable distribution of interns among hospitals. In addition, there is assurance of better training for the future general practitioner, and the residency program is simplified.

The Committee recommends that hospitals be encouraged to adopt a two-year internship as outlined above.

NEW YORK STATE MEDICAL LIBRARY

Doctors of New York State are reminded of the facilities of the State Medical Library at Albany. They are invited to visit, telephone, or write to the Library where a trained staff of librarians will take care of their requests.

Upon request, a copy of the regulations will be sent, which lists the services of the Library, including the compiling of bibliographies, sending material on specific subjects, or filling requests for definite book or journal references.

A collection of over 57,000 books and the receipt of approximately 600 current medical journals enable the Medical Library to offer a real service to the doctors of the State.

Letters may be addressed to Miss Maude E. Nesbit, Librarian, New York State Medical Library, Education Building, Albany 1, New York.

Special Article

SUGGESTIONS TO IMPROVE INTERN AND RESIDENCY TRAINING AND TO FACILITATE INTERN PLACEMENT BY REARRANGEMENT OF SCHEDULE

Report of Subcommittee of the New York Committee on the Study of Hospital Internships and Residencies

CARL EGGERS, M.D., *Chairman*, WILLIAM W. BECKMAN, M.D., and LINDSLEY F. COCHEU, M.D., New York City

(*Subcommittee, New York Committee on the Study of Hospital Internships and Residencies*)

WITH the onset of the last war the intern schedules existing at the time were seriously upset and modified by the demands of the armed forces for medical officers. The majority of the graduates were allowed to serve only a nine-month internship. The educational opportunities offered them during their military service varied a great deal. Some men had the good fortune to be assigned to units which offered an opportunity for study and practice, while others served as field officers with less opportunity to improve themselves. The result was that a large percentage of discharged medical officers required further education and sought appointments as interns, residents, or laboratory assistants, while others participated in refresher courses. Eventually, all the men were absorbed and found their place in more or less satisfactory positions in life.

During the war, home medical institutions were affected by reduction in teaching staffs, laboratory personnel, and intern assignments. At the termination of hostilities many hospitals did not return to the same type of an internship they had formerly had. A one-year internship was largely accepted. This was due partly to the fact that hospitals had become accustomed to a short rotating internship and partly to the fact that specialty boards required only a one-year internship prior to training in a specialty, with expansion of residencies at the expense of more prolonged internships. In addition, medical officers had become conscious of the advantages which certification in a specialty offered during war time. The demand for special training, therefore, increased enormously to the detriment of training for general practice.

These different factors have contributed to the present confused situation concerning internships and have complicated still further the problem of intern placement. This year's results in the national placement program were disappointing to the hospitals because there was an insufficient number of graduates available for the total number of internships offered (5,100 medical graduates for 9,118 internships).* The current shortage of interns among civilian hospitals is due to several factors. There are more approved internships available than there were before the war, and the institutions which formerly had a two-year internship now require twice as many men annually for their one-year internships. It is further accentuated by the number of medical men taken annually by the Army and Navy hospitals (over 10 per cent of the graduates).

* 1948–1949 figures.

To find a solution for these problems and, at the same time, to assure adequate basic practical training to interns and residents is most important. The problem is the same, whether they expect to engage in general or family practice or whether they desire to prepare themselves for the practice of a specialty. The training of interns and residents must be considered a joint problem. Cooperation between medical schools, hospitals, and other interested organizations is essential.

The New York Committee on the Study of Hospital Internships and Residencies is interested in the placement of interns and residents, their education,

was a member of the Chemung County and New York State Medical Societies and the American Medical Association.

Albert Ferdinand Soch, M.D., of Fredonia, died on October 30 at the Buffalo General Hospital at the age of seventy-eight. Dr. Soch was graduated from the University of Buffalo School of Medicine in 1897 and interned at the Erie County Hospital. Since 1900 he had been in general practice in Fredonia. In 1948 Dr. Soch was honored by the Medical Society of the State of New York for having completed fifty years of service as a physician. He was an honorary staff member of the Brooks Memorial Hospital in Dunkirk and a member of the Chautauqua County and New York State Medical Societies and the American Medical Association.

Davis S. Warner, M.D., of Center Moriches, died on November 13 at the age of eighty-five. Dr. Warner was graduated from the College of Physicians and Surgeons, Columbia University, in 1888, and had practiced for forty years in Center Moriches before retiring about twenty years ago. He first made his rounds with a bicycle and later with a horse and buggy.

Russell H. Wilcox, M.D., of Tonawanda, died on October 9 at the age of sixty-seven. Dr. Wilcox was graduated from the University of Buffalo School of Medicine in 1906. He was attending physician on the staff of the De Graff Memorial Hospital in North Tonawanda and was a member of the Buffalo Academy of Medicine, the Twin City Academy of Medicine, the Erie County and New York State Medical Societies, and the American Medical Association.

SCIENTIFIC EXHIBITS
1950
ANNUAL MEETING

Applications for space for the scientific exhibits should be made directly to the Chairman of the Subcommittee on Scientific Exhibits of the Convention Committee:

Dr. J. G. Fred Hiss
505 State Tower Building
Syracuse 2, New York

The Annual Meeting will be held May 8 to 12, 1950, at the Hotel Statler in New York City.

No applications can be considered after January 15, 1950

There will be two groups of awards:

Awards in Group I are made for exhibits of individual investigation, which are judged on the basis of originality and excellence of presentation.

Awards in Group II are made for exhibits which do not exemplify purely experimental studies and which are judged on the basis of excellence of presentation and correlation of facts.

W. P. Anderton, M.D., *Secretary*

NECROLOGY

Arnold I. Bricker, M.D., of Brooklyn, died in August. Dr. Bricker was graduated from the Long Island College of Medicine in 1947 and was a resident in radiology at the Beth-El Hospital in Brooklyn. He was an intern member of the Kings County Medical Society.

Francis Joseph d'Avignon, M.D., of Lake Placid, died suddenly on November 3 while on a hunting trip in Canada. He was sixty-four. Dr. d'Avignon received his medical degree from the McGill University College of Medicine in 1909 and had practiced in Lake Placid for many years. He was attending surgeon at the Lake Placid General Hospital. Dr. d'Avignon was a member of the Essex County and New York State Medical Societies and the American Medical Association.

Emery Alexander de Bardoly, M.D., of New York City and Manhasset, died on November 11 at his home in Manhasset at the age of forty-eight. Dr. de Bardoly, a native of Hungary, received his medical degree from the University of Budapest in 1925 and came to the United States before World War II. During the war he served as a captain in the U.S. Army Medical Corps in the Asiatic theater. He was stationed in Tokyo when General Hideki Tojo, wartime Japanese Premier, later executed, made his suicide attempt, and Dr. de Bardoly participated in his care. Dr. de Bardoly was president of and physician to the Verhozay Society, an association of Hungarian-Americans.

Walter R. Grunewald, M.D., of Mayfield, died on November 10 at his home at the age of sixty. Dr. Grunewald was graduated from the Albany Medical College in 1912 and had formerly practiced in Cohoes and Crescent. Dr. Grunewald, who moved to Mayfield in 1920, was assistant physician at the Nathan Littauer Hospital in Gloversville and had served as Fulton County coroner for the past twenty-seven years, having been re-elected to the position in the November 8 elections. He was a member of the Fulton County and New York State Medical Societies and the American Medical Association.

Lester Mead Hubby, M.D., of New York City, died on November 10 at his home after a brief illness, at the age of seventy-eight. Dr. Hubby was graduated from the New York University Medical College in 1896. During World War I he served as a major at the American Red Cross Hospital in Paris under Dr. Joseph Blake. Dr. Hubby was consulting otolaryngologist at the Harlem and Manhattan Eye, Ear, and Throat Hospitals, and consulting surgeon of the Northern Dispensary of the City of New York.

A Fellow of the American College of Surgeons and a Diplomate of the American Board of Otolaryngology, Dr. Hubby was a member of the American Laryngological, Rhinological, and Otological Society, the American Otological Society, the New York Otological Society, the New York Academy of Medicine, the New York County and State Medical Societies, and the American Medical Association.

George Albert Lane, Jr., M.D., of Rochester, died on October 31 at the age of seventy-four. Dr. Lane was graduated from the University of Buffalo School of Medicine in 1896. He practiced in Rochester for many years before his retirement about twenty years ago.

Frederick L. McCrea, M.D., of Port Jefferson, died on November 11 at his home at the age of sixty-eight. Dr. McCrea was graduated from the Long Island College Hospital in 1907 and had been practicing in Port Jefferson for the past forty-one years. He was chief of the obstetric staff of Mather Memorial Hospital in Port Jefferson and was a past president of the hospital's medical board. Dr. McCrea was a member of the Suffolk County and New York State Medical Societies and the American Medical Association.

Russell Addison Millar, M.D., of Williston Park, died suddenly on October 30 at the age of forty-four. Dr. Millar was graduated from the Long Island College Hospital in 1930. During World War II he served with the Navy Medical Corps as a lieutenant commander and was overseas in the Pacific theater. Dr. Millar was assistant pediatrician at the Nassau Hospital in Mineola and was an associate on the staff of the North Country Community Hospital in Glen Cove. He was a member of the Nassau County and New York State Medical Societies and the American Medical Association.

Christian William Schmidt, M.D., of Montour Falls, died on November 3 at the Arnot-Ogden Hospital in Elmira at the age of forty-seven. Dr. Schmidt was graduated from the Syracuse University College of Medicine in 1934. He was secretary-treasurer of the Schuyler County Medical Society and a member of that group, the New York State Medical Society, and the American Medical Association.

Samuel Maxwell Seafuse, M.D., of Elmira, died on October 29 at the age of eighty. Dr. Seafuse was graduated from the College of Physicians and Surgeons in Baltimore in 1893 and was honored several years ago by the Medical Society of the State of New York on his completion of fifty years of service as a physician. Dr. Seafuse began his practice in Gillett, Pennsylvania, before moving to Elmira, where he practiced for more than forty years. He

was a member of the Chemung County and New York State Medical Societies and the American Medical Association.

Albert Ferdinand Soch, M.D., of Fredonia, died on October 30 at the Buffalo General Hospital at the age of seventy-eight. Dr. Soch was graduated from the University of Buffalo School of Medicine in 1897 and interned at the Erie County Hospital. Since 1900 he had been in general practice in Fredonia. In 1948 Dr. Soch was honored by the Medical Society of the State of New York for having completed fifty years of service as a physician. He was an honorary staff member of the Brooks Memorial Hospital in Dunkirk and a member of the Chautauqua County and New York State Medical Societies and the American Medical Association.

Davis S. Warner, M.D., of Center Moriches, died on November 13 at the age of eighty-five. Dr. Warner was graduated from the College of Physicians and Surgeons, Columbia University, in 1888, and had practiced for forty years in Center Moriches before retiring about twenty years ago. He first made his rounds with a bicycle and later with a horse and buggy.

Russell H. Wilcox, M.D., of Tonawanda, died on October 9 at the age of sixty-seven. Dr. Wilcox was graduated from the University of Buffalo School of Medicine in 1906. He was attending physician on the staff of the De Graff Memorial Hospital in North Tonawanda and was a member of the Buffalo Academy of Medicine, the Twin City Academy of Medicine, the Erie County and New York State Medical Societies, and the American Medical Association.

CORRESPONDENCE

Medical Terminology

To the Editor:

In the October 1, 1949, issue of the JOURNAL on page 2318 there appears an interesting article on the uselessness of the term "essentially" in reports and statements by the medical profession. May I nominate a few others which are not only terribly overworked but often result in harm to the patient and in a poor understanding of his condition.

First on the list is the word "normal," apparently in the sense that a certain finding falls within an arbitrary interval of maximum and minimum. Such a standard may be statistically valid but need not apply to a particular case, especially when viewed in relation to other individual factors, which, of course, were not taken into account when the "normal" standard was set. Since "normal" findings are generally blindly dismissed as inconsequential, serious errors in judgment are not infrequent.

"Routine" is another such term acting as a mental narcotic. No enlargement on this statement seems necessary.

With the introduction of the many and constantly increasing number of tests and signs, al breviations to initials of procedures and result are gaining in popularity. Unquestionably thi saves much time and paper space, and this practic should not be abolished. As one reflects, howeve on its effect on constructive and observationa medical thinking, one cannot escape the convictio that it, too, acts to quite an extent as a menta narcotic. The original significance of the procedur and the inferences which it was supposed to permi become greatly dulled in incisiveness, and much o its possible use may be lost. One questions whethe this saving of space and time is not really bought at too high a price. I venture to say, too, that many uselessly ordered tests would not be asked for if the term "routine" were used more sparingly and abbreviations were reduced in hospital practice.

Sigmoidal Endometriosis

To the Editor:

In recent article on "Endometriosis of the Sigmoid," by Paul F. Berlin and Edward O. Finestone [NEW YORK STATE J. MED. 49: 2081 (Sept. 1) 1949], I was interested to note that a resection of the sigmoid was done for the endometriosis.

I would like to inquire of Doctors Berlin and Finestone as to the indications for such a resection in view of the fact that complete regression of such lesions usually occurs following simple bilateral oöphorectomy. I refer particularly to such standard textbooks as Wharton's *Gynecology*, Crossen and Crossen's *Diseases of Women*, and Goodall's *Endometriosis*.

I feel that the authors were unnecessarily radical but would like the point clarified.

HOWARD S. MORROW, M.D.

Crane Road
Mahopac, New York
October 14, 1949

Reply by Dr. Finestone

To the Editor:

In compliance with your request, I will attempt to answer the queries made by Dr. Morrow in his communication of October 14, 1949. The authors of the article, "Endometriosis of the Sigmoid," were quite cognizant of the fact that "complete regression of such lesions occurs following simple bilateral oöphorectomy." Indeed, a bilateral oöphorectomy was performed.

It is well known that, in lesions of the stomach with ulceration, it is virtually impossible to tell at operation, when the organ is seen and felt by the surgeon, whether he is dealing with a benign ulcer or a malignancy. Only a biopsy can decide this issue.

In this case, a well recognized pathologist was at hand for this very purpose, but it is impossible to take a biopsy of the colon without cutting through all its layers. Moreoever, in the case reported, the lesion was so indurated and had involved all the coats of the bowel to such an extent that it produced a marked stenosis. Therefore, it occurred to the authors that the fibrotic reaction resulting from the repeated hemorrhages incident to the endometriosis would not subside with castration alone. Therefore, a bowel resection was indicated. In the final analysis, where doubt exists as to a probable malignancy even though there is an associated benign condition, resection is deemed most advisable. A definitive biopsy was unobtainable by sigmoidoscopy before operation.

October 31, 1949

Proposed Treatment of Radiosensitive Tumors with Repository Containing Radioactive Isotope

To the Editor:

When a substance is injected into the body and requires an extended length of time, say from about six hours to a week or more, to be completely absorbed, we speak of a repository or a depot of the substance. Repository therapy was used for a long time in the treatment of syphilis in the form of suspensions of mercury and bismuth salts in oil. Suspensions of estrogen in water give a prolonged action upon injection owing to repository formation.

In the early days of penicillin, injections of soluble sodium penicillin were given every four hours. Ways were sought to prolong its action by means of creating repositories. Romansky and Rittman in 1944 did this by mixing the sodium penicillin with oil and wax.[1] In 1947 the writer described a series of water insoluble penicillin salts, both organic and inorganic, which could be used as repository therapy to give prolonged blood levels.[2] The most widely used penicillin derivative at the present time, procaine penicillin, owes its repository action to its water insolubility.

What are the requirements of a substance to be used in repository therapy? Any substance, inorganic or organic, is suitable for such use, if it is substantially insoluble in water and is completely absorbable. Water-soluble substances as such are unsuitable unless mixed with a protective colloid such as wax or pectin to slow their absorption. A repository substance may be used in the solid form, as, for example, an estrogen implant; it may be injected suspended in water, or in oil if it is also insoluble in oil; it may be dissolved in diluted ethyl alcohol or some other nontoxic water-miscible solvent and then injected. The alcohol or other solvent is quickly absorbed, leaving the water-insoluble repository in situ. I have lately injected subcutaneously water-insoluble procaine base in aqueous suspension and in solution in 50 per cent ethyl alcohol to produce repositories resulting in anesthesia of the overlying skin for a period of two weeks and more or until the procaine was completely absorbed.[3]

The duration of a repository depends upon a number of factors, among which may be mentioned the degree of water insolubility of the substance used, the size of its particles, its concentration in the menstruum, the type of menstruum, the presence of protective colloids, and the vascularity of the tissue into which it has been injected. By varying these factors it is possible to produce repositories varying in duration of absorption from a few hours to two weeks and more.

If we use a repository substance, with a radioactive isotope taking the place of one or more of its normal atoms, we have at our disposal the means of introducing by injection or otherwise a radioactive substance into any area of the body and keeping it there a definite length of time. The latter will depend on either the duration of the repository or the life of the radioactive isotope or both. If, for example, the isotope Bismuth 210, with a half-life of five days, is used, most of the radioactivity will disappear before the entire repository has been absorbed. The opposite is true of long life isotopes. With the latter, such as carbon, it is necessary to use a repository which is completely eliminated, so that with complete absorption of the repository there should be no more radioactive isotope present in the body.

Suggested repositories are procaine base, especially valuable because of its anesthetic and pain-dulling effect as long as it remains present. In addition it is hydrolyzed by the body into para-aminobenzoic acid and diethylaminoethanol. Practically all of the former is quickly eliminated in the urine after absorption from the repository. The radioactive isotope should therefore be placed in the para-aminobenzoic acid fraction of the procaine base molecule.

The various salts of penicillin, especially the procaine and iron salts, are also suitable. In addition one may use bismuth subcarbonate or subnitrate, calcium carbonate, mono- or dicalcium phosphate, iron carbonate, iron phosphate, and barium or calcium sulfate.

Considerable work would have to be done to determine the proper dosage of such radioactive repositories. With this knowledge, however, tumors can be treated by injection, first around their periphery to prevent metastasis and then directly into the growth itself; suspicious areas during operation can be injected; lymph nodes can be neutralized; the thyroid area can be directly injected; epitheliomata of the skin can be undermined; radioactive phosphorus can be introduced directly into the bone marrow or spleen and a radioactive repository mist can be instilled into the lungs.

I myself have not the facilities to do work of this type but think my suggestions are valid and should stimulate work along these lines.

Medical Terminology

To the Editor:

In the October 1, 1949, issue of the JOURNAL on page 2318 there appears an interesting article on the uselessness of the term "essentially" in reports and statements by the medical profession. May I nominate a few others which are not only terribly overworked but often result in harm to the patient and in a poor understanding of his condition.

First on the list is the word "normal," apparently in the sense that a certain finding falls within an arbitrary interval of maximum and minimum. Such a standard may be statistically valid but need not apply to a particular case, especially when viewed in relation to other individual factors, which, of course, were not taken into account when the "normal" standard was set. Since "normal" findings are generally blindly dismissed as inconsequential, serious errors in judgment are not infrequent.

"Routine" is another such term acting as a mental narcotic. No enlargement on this statement seems necessary.

With the introduction of the many and constantly increasing number of tests and signs, abbreviations to initials of procedures and results are gaining in popularity. Unquestionably this saves much time and paper space, and this practice should not be abolished. As one reflects, however, on its effect on constructive and observational medical thinking, one cannot escape the conviction that it, too, acts to quite an extent as a mental narcotic. The original significance of the procedure and the inferences which it was supposed to permit become greatly dulled in incisiveness, and much of its possible use may be lost. One questions whether this saving of space and time is not really bought at too high a price. I venture to say, too, that many uselessly ordered tests would not be asked for if the term "routine" were used more sparingly and abbreviations were reduced in hospital practice.

Sigmoidal Endometriosis

To the Editor:

In recent article on "Endometriosis of the Sigmoid," by Paul F. Berlin and Edward O. Finestone [NEW YORK STATE J. MED. 49: 2081 (Sept. 1) 1949], I was interested to note that a resection of the sigmoid was done for the endometriosis.

I would like to inquire of Doctors Berlin and Finestone as to the indications for such a resection in view of the fact that complete regression of such lesions usually occurs following simple bilateral oöphorectomy. I refer particularly to such standard textbooks as Wharton's *Gynecology*, Crossen and Crossen's *Diseases of Women*, and Goodall's *Endometriosis*.

I feel that the authors were unnecessarily radical but would like the point clarified.

HOWARD S. MORROW, M.D.

Crane Road
Mahopac, New York
October 14, 1949

Reply by Dr. Finestone

To the Editor:

In compliance with your request, I will attempt to answer the queries made by Dr. Morrow in his communication of October 14, 1949. The authors of the article, "Endometriosis of the Sigmoid," were quite cognizant of the fact that "complete regression of such lesions occurs following simple bilateral oöphorectomy." Indeed, a bilateral oöphorectomy was performed.

It is well known that, in lesions of the stomach with ulceration, it is virtually impossible to tell at operation, when the organ is seen and felt by the surgeon, whether he is dealing with a benign ulcer or a malignancy. Only a biopsy can decide this issue.

In this case, a well recognized pathologist was at hand for this very purpose, but it is impossible to take a biopsy of the colon without cutting through all its layers. Moreoever, in the case reported, the lesion was so indurated and had involved all the coats of the bowel to such an extent that it produced a marked stenosis. Therefore, it occurred to the authors that the fibrotic reaction resulting from the repeated hemorrhages incident to the endometriosis would not subside with castration alone. Therefore, a bowel resection was indicated. In the final analysis, where doubt exists as to a probable malignancy even though there is an associated benign condition, resection is deemed most advisable. A definitive biopsy was unobtainable by sigmoidoscopy before operation.

DEPARTMENT OF MEDICAL CARE INSURANCE

CONDUCTED BY GEORGE P. FARRELL, DIRECTOR

Membership in Medical Care Plans Approaching Two Million

AS OF September 30, 1949, membership in the voluntary nonprofit medical care insurance plans in New York State (approved by the Medical Society of the State of New York) was 1,987,104, an increase of 447,845 members for the nine-month period. Payments for benefits to members was $6,652,277, an increase of $2,453,196, or 58 per cent more than the corresponding period a year ago.

After discussion, *it was voted* that the matter of employing a legislative representative be laid on the table, on account of other unexpected expenses.

Problems of Alcoholism.—Dr. Milton G. Potter, chairman, wrote Dr. Anderton on October 10, 1949, and enclosed a copy of the third report of the Subcommittee on Problems of Alcoholism to the Interdepartmental Health Council of New York State. This report approves continuation of the clinic for the care and rehabilitation of the chronic alcoholic patient which is being conducted under the auspices of the University of Buffalo School of Medicine in Buffalo. It also proposes that a bill similar to the following be introduced in the 1950 State Legislature. Dr. Potter requests "approval of the draft by the Council at this time," and that it be introduced under the auspices of the Medical Society of the State of New York.

DRAFT OF PROPOSED BILL

"Control of Chronic Alcoholism"

The Commissioner of Health is hereby authorized to establish, equip, maintain, and conduct a demonstration program designed to determine adequate methods for the care and rehabilitation of persons suffering from chronic alcohol addiction; to carry out such educational and research activities as he may deem necessary in connection with the said program; to encourage and assist local communities in establishing and maintaining outpatient services for rehabilitable alcoholic addicts, and to establish necessary rules and regulations to effect the purpose of this act.

The Commissioner may conduct this program solely as a State activity or in cooperation with such institutions, hospitals, or municipal corporations as he may select, on such terms as they agree upon.

The sum of $150,000 or as much thereof as may be necessary is hereby appropriated to the Department of Health for the purpose of carrying out the provisions of this section of the Public Health Law as added by this act.

This act will take effect April 1, 1950.

It was voted to approve the report.

Economics.—Dr. Azzari, chairman, reported regarding meetings which Mr. Farrell, Director of the Bureau of Medical Care Insurance, had attended. He stated that financial and membership statements about the New York State plans for the years 1946, 1947, and 1948 and to June 30, 1949, had been distributed at the district branch meetings and included in his report to the Council as published in the agenda of the meeting.

Dr. Azzari reported regarding several matters referred to the Economics Committee, as follows:

Income Tax Allowance for National Health Insurance (the Linowitz Plan).—The Committee recommended this should be studied further. The Council granted permission.

Practice of Medicine by Hospitals.—Dr. Azzari stated that it continued to be the feeling of the Committee on Economics that it would be unwise to have a conference with deans of medical schools and representatives of teaching institutions at this time.

After discussion, *it was voted* that no action be taken at this time.

Group Health Insurance, Inc.—The Committee studied this plan and the application of this Group for endorsement by the State Society and makes no recommendation as to approval, following the established policy of referring such groups to the respective county societies first, for endorsement.

After discussion, *it was voted* that the Group Health Insurance, Inc., be notified that the proper procedure for them to follow would be to request the county societies, in the area in which they operate, to give endorsement.

Annual General Practitioner's Award—The Committee received from the Secretary the nominations of two men from county societies for the Annual General Practitioner's Award to be submitted to the American Medical Association. The Committee felt that it was unfortunate that there were only two, because both are very worthy men.

After discussion, *it was voted* to nominate Dr. John R. MacElroy of Saratoga County for the Annual General Practitioner's Award of the American Medical Association.

Public Medical Care—Dr. Anderton stated that Dr. Stephen R. Monteith, chairman of the Public Medical Care Subcommittee, recommends approval of the second edition of the *Drug Manual* issued by the Onondaga County Department of Welfare.

Approval was voted.

Malpractice Insurance and Defense Board.—A member appeared before the Council in regard to his petition that the Council reconsider its vote not to renew his malpractice insurance under the Society's group policy.

It was unanimously voted that the recommendation of the Malpractice Insurance and Defense Board be adopted as follows: In view of the rather unfavorable record that this member has had in regard to malpractice insurance, thereby throwing an undue burden on the rest of the members insured, that he be denied the privilege of re-insurance in the Malpractice Insurance Plan at the expiration of his present contract.

Publication.—Dr. Kosmak reported that the Committee met on October 12, 1949. Changes in the advertising department of the JOURNAL and *Directory* necessitated much discussion. It was believed desirable to increase our present staff of advertising solicitors to include the West Coast and the Middle West, so that eventually we will have five salesmen instead of two.

Mr. Anderson's visit to Chicago recently was productive of complimentary statements as regards the advertising value of the JOURNAL, and, notwithstanding the depressed situation in the advertising field, we are glad to report that, as far as the JOURNAL is concerned, there has been no diminution but rather a certain increase. Of course, that will be balanced by the fact that the expense of publishing the JOURNAL during the coming year is largely increased. We have also found it desirable to use a heavier quality of paper, and I think that will reflect favorably on the advertisers as well as the readers of the JOURNAL.

The budget for the year was thoroughly discussed. Dr. Reuling will report about it later.

We also decided on an increase in advertising rates of 10 per cent both for the JOURNAL and the *Directory*.

In view of the fact that the New Jersey and Connecticut physicians are to be omitted from the next *Directory*, we considered that we would have to change the title to the *Medical Directory of New*

SUMMARY OF MINUTES OF THE COUNCIL OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

AT ITS meeting on October 13, 1949, the Council considered the following matters, taking action as indicated.

Secretary's Report

Remission of Assessments.—Remission of annual assessments was voted on account of service with the armed forces for one member for 1948; on account of illness for three members; also, War Memorial assessment on account of illness for one member.

Communications.—1. Letter dated September 6, 1949, from Mr. Frederick F. Stevens, President, New York State Pharmaceutical Association, to President Masterson, requesting that the Medical Society of the State of New York appoint a committee to act in conjunction with one from their society.

It was voted to approve a joint committee of the Medical Society of the State of New York and the New York State Pharmaceutical Association and that Dr. Masterson be empowered to negotiate with the President of the New York State Pharmaceutical Association to decide the size of the committee and to appoint our members.

2. Letter of September 7, 1949, from Dr. Carl M. Peterson, Secretary, Council on Industrial Health, American Medical Association, requesting that the Medical Society of the State of New York cosponsor the Tenth Annual Congress on Industrial Health at the Hotel Roosevelt, New York City, on February 20 and 21, 1950.

It was voted to act as a cosponsor.

3. Letter of October 4, 1949, from Miss Clara Quereau, Secretary, Board of Examiners of Nurses, to Dr. Anderton, requesting two or more nominations for a vacancy on the Nurse Advisory Council of the New York State Department of Education.

Dr. W. P. Anderton and Dr. W. Guernsey Frey, Jr., were nominated.

4. Letter of October 5, 1949, from Dr. Herman E. Hilleboe, New York State Commissioner of Health, acknowledging letter of September 27, 1949, sent by the Secretary regarding action taken by the Council on the report of the Committee on Problems of Alcoholism.

Activities.—The Secretary detailed his attendance at district branch meetings and announced that the annual meeting of county society secretaries was to be held November 2, 1949, at the Hotel Ten Eyck, Albany.

He also reported that President Masterson had him notify Dr. James A. Lynch, Bronx, that he has been appointed on the Legislation Committee; Dr. David S. Ruhe and Dr. Granville Larimore, New York State Department of Health, Albany, that they were advisory members of the Subcommittee on Medical Film Review of the Public Health and Education Committee; and Dr. Irving J. Sands, Brooklyn, that he is a member of the Mental Hygiene Subcommittee of the Public Health and Education Committee.

At the request of Mr. Robert W. Osborn, secretary of the Committee on Tuberculosis and Public Health of the State Charities Aid Association, Dr. Theodore J. Curphey, chairman of the Committee on Public Health and Education, was requested to represent the Society at the first meeting of the Heart Advisory Committee to the State Executive Committee of the Committee on Tuberculosis and Public Health of the State Charities Aid Association. The Secretary suggested that this request be approved and that Dr. Curphey be designated as representative on this Heart Advisory Committee.

Approval was voted.

Furthermore, Dr. Anderton reported that during the past month there had been an unusual number of physicians who called in regard to localities in New York State desiring a general practitioner. Having visited eleven such localities during his recent vacation, the Secretary reported he was able to be of help.

Also, President Masterson requested the Secretary to represent the Society on the Citizens Committee on Hospital Bond Issue for New York State.

Approval was voted.

The Secretary announced that Mr. Bernard McDermott, president of the Hospital Association of New York State, has appointed the members of his Executive Committee to represent the association on the Joint Committee of the Hospital Association of New York State and the Medical Society of the State of New York. These gentlemen are: Messrs. Carl P. Wright, Carl P. Wright, Jr., Lawrence E. Kresge, and Moir Tanner.

On October 10, 1949, the Secretary represented the Society at the laying of the cornerstone of the Bird S. Coler Memorial Hospital for Chronic Diseases on Welfare Island, New York City.

The sudden death of Mrs. Edgar M. Neptune, last year's president of the Woman's Auxiliary, was reported. Flowers were sent to her funeral in the name of the Society and a letter of sympathy to Dr. Neptune.

The Treasurer's report was accepted.

Report of the Executive Officer

Dr. Hannon reported his attendance at district branch meetings and at a special meeting of the Subcommittee on Legislation. He reported he had been in contact with representatives of the Department of Education, the Dental Society, the Podiatry Society, and the Optometrists Association in regard to proposed legislation.

Reports of Committees

Legislation.—Dr. Dattelbaum, chairman, reported as follows:

Following the approval of the Council, the Chairman and Executive Officer have continued to work on its recommendations which were approved by the Council and to stimulate the subcommittees of the Legislative Committee to carry out their assignments. Contacts have been made through members of these subcommittees with various legislators, representatives of different State departments, and representatives of other professions.

On September 20, 1949, a subcommittee of the Legislation Committee met at the State Society office to discuss the proposed employment of an additional full-time legislative representative.

After discussion, *it was voted* that the matter of employing a legislative representative be laid on the table, on account of other unexpected expenses.

Problems of Alcoholism.—Dr. Milton G. Potter, chairman, wrote Dr. Anderton on October 10, 1949, and enclosed a copy of the third report of the Subcommittee on Problems of Alcoholism to the Interdepartmental Health Council of New York State. This report approves continuation of the clinic for the care and rehabilitation of the chronic alcoholic patient which is being conducted under the auspices of the University of Buffalo School of Medicine in Buffalo. It also proposes that a bill similar to the following be introduced in the 1950 State Legislature. Dr. Potter requests "approval of the draft by the Council at this time," and that it be introduced under the auspices of the Medical Society of the State of New York.

DRAFT OF PROPOSED BILL

"Control of Chronic Alcoholism"

The Commissioner of Health is hereby authorized to establish, equip, maintain, and conduct a demonstration program designed to determine adequate methods for the care and rehabilitation of persons suffering from chronic alcohol addiction; to carry out such educational and research activities as he may deem necessary in connection with the said program; to encourage and assist local communities in establishing and maintaining outpatient services for rehabilitable alcoholic addicts, and to establish necessary rules and regulations to effect the purpose of this act.

The Commissioner may conduct this program solely as a State activity or in cooperation with such institutions, hospitals, or municipal corporations as he may select, on such terms as they agree upon.

The sum of $150,000 or as much thereof as may be necessary is hereby appropriated to the Department of Health for the purpose of carrying out the provisions of this section of the Public Health Law as added by this act.

This act will take effect April 1, 1950.

It was voted to approve the report.

Economics.—Dr. Azzari, chairman, reported regarding meetings which Mr. Farrell, Director of the Bureau of Medical Care Insurance, had attended. He stated that financial and membership statements about the New York State plans for the years 1946, 1947, and 1948 and to June 30, 1949, had been distributed at the district branch meetings and included in his report to the Council as published in the agenda of the meeting.

Dr. Azzari reported regarding several matters referred to the Economics Committee, as follows:

Income Tax Allowance for National Health Insurance (the Linowitz Plan).—The Committee recommended this should be studied further. The Council granted permission.

Practice of Medicine by Hospitals.—Dr. Azzari stated that it continued to be the feeling of the Committee on Economics that it would be unwise to have a conference with deans of medical schools and representatives of teaching institutions at this time.

After discussion, *it was voted* that no action be taken at this time.

Group Health Insurance, Inc.—The Committee studied this plan and the application of this Group for endorsement by the State Society and makes no recommendation as to approval, following the established policy of referring such groups to the respective county societies first, for endorsement.

After discussion, *it was voted* that the Group Health Insurance, Inc., be notified that the proper procedure for them to follow would be to request the county societies, in the area in which they operate, to give endorsement.

Annual General Practitioner's Award—The Committee received from the Secretary the nominations of two men from county societies for the Annual General Practitioner's Award to be submitted to the American Medical Association. The Committee felt that it was unfortunate that there were only two, because both are very worthy men.

After discussion, *it was voted* to nominate Dr. John R. MacElroy of Saratoga County for the Annual General Practitioner's Award of the American Medical Association.

Public Medical Care—Dr. Anderton stated that Dr. Stephen R. Monteith, chairman of the Public Medical Care Subcommittee, recommends approval of the second edition of the *Drug Manual* issued by the Onondaga County Department of Welfare.

Approval was voted.

Malpractice Insurance and Defense Board.—A member appeared before the Council in regard to his petition that the Council reconsider its vote not to renew his malpractice insurance under the Society's group policy.

It was unanimously voted that the recommendation of the Malpractice Insurance and Defense Board be adopted as follows: In view of the rather unfavorable record that this member has had in regard to malpractice insurance, thereby throwing an undue burden on the rest of the members insured, that he be denied the privilege of re-insurance in the Malpractice Insurance Plan at the expiration of his present contract.

Publication.—Dr. Kosmak reported that the Committee met on October 12, 1949. Changes in the advertising department of the JOURNAL and *Directory* necessitated much discussion. It was believed desirable to increase our present staff of advertising solicitors to include the West Coast and the Middle West, so that eventually we will have five salesmen instead of two.

Mr. Anderson's visit to Chicago recently was productive of complimentary statements as regards the advertising value of the JOURNAL, and, notwithstanding the depressed situation in the advertising field, we are glad to report that, as far as the JOURNAL is concerned, there has been no diminution but rather a certain increase. Of course, that will be balanced by the fact that the expense of publishing the JOURNAL during the coming year is largely increased. We have also found it desirable to use a heavier quality of paper, and I think that will reflect favorably on the advertisers as well as the readers of the JOURNAL.

The budget for the year was thoroughly discussed. Dr. Reuling will report about it later.

We also decided on an increase in advertising rates of 10 per cent both for the JOURNAL and the *Directory*.

In view of the fact that the New Jersey and Connecticut physicians are to be omitted from the next *Directory*, we considered that we would have to change the title to the *Medical Directory of New*

York State. The Committee plans to extend the value of this book by inserting a considerable amount of material of interest to physicians, which will make them refer to the book more often and so increase its value to advertisers. That matter is still under discussion.

We hope that the next *Directory* will appear in December, 1950, and will be known as the 1951 edition.

Public Health and Education.—Dr. Curphey, chairman, sent a report stating he had attended meetings of subcommittees and arranged for post-graduate instruction and teaching days for several counties.

In connection with the activities of the Subcommittee on Cerebral Palsy, it was recommended that Dr. George W. Kosmak be included as a member.

It was voted that the recommendation be approved.

Public Relations.—Dr. Winslow, chairman, reported that during the past month the Public Relations Bureau took steps to reactivate the full-scale field program that had been halted temporarily during the summer. Mr. Leech, Mr. Tracey, and Mr. Weinrich returned to their stations and resumed activities. Coordination of the field program was placed in charge of Mr. Miebach, while Mr. Walsh was assigned to the speakers bureau and the Woman's Auxiliary.

He also reported on the various activities that took place during the month, such as releases on district branch meetings, publicizing an article in *Look* magazine, and Dr. Louis H. Bauer's speech to the National Association of Retail Druggists.

Veterans Administration, Liaison with.—Dr. Anderton reported that the contract between Veterans Medical Care Plan of New York, Inc., and the U. S. Veterans Administration had been extended for a year and that the salaries of the Coordinators had been reduced one quarter.

Woman's Auxiliary.—Dr. Beekman, chairman, reported as follows: As the National Education Campaign gains momentum, the value of the part our woman's auxiliaries, both State and county, are playing in relaying the medical profession's message to the American public becomes more evident.

Therefore, it is recommended that the Council authorize the Secretary to prepare a letter to the presidents of the county medical societi letter should contain the suggestion that, practical, the chairman of each county State public relations committees extend tion to the chairman of the respective auxiliaries' public relations committees the meetings of his committee.

Approval was voted.

Workmen's Compensation.—Dr. Kenne man, reported on the activities of the Com

New Business

Appointment of Committee on Histor Medical Society of the State of New Y Anderton reported as follows: A Speci mittee on the History of the Medical Socie State of New York has been previousl mended and has been considered in confe several members. Dr. Redway has writte President suggesting that such committee Dr. Fenwick Beekman, chairman, Dr. N Van Etten, Dr. W. P. Anderton, Dr. Lau Redway, and Dr. James F. Rooney, w Dougherty as recorder.

It was voted that the Council request the I to appoint this committee.

The President so appointed.

Judge Proctor's Charge to the Jury in Case.—Judge Proctor states in simple a language what a membership society can an do.

It was voted to send a letter from President son to the president and secretary of eac society with a copy of Judge Proctor's char jury in the suit of the Department of against the Washington, D.C., Medical and the A.M.A. some years ago.

Political.—As the result of a memorandu by Dr. Anderton,

It was voted to adhere to the policy that t ical Society of the State of New York d take active part as an organization in any campaign.

VITAMIN B_{12}, EXERCISES AID VICTIMS OF PERNICIOUS ANEMIA

Spinal cord degeneration, which is one of the most sinister complications of pernicious anemia, can be reversed if treatment with vitamin B_{12} and exercises is begun early enough, say three doctors from the Mayo Clinic, Rochester, Minnesota.

"Our study indicates that degeneration of the spinal cord associated with pernicious anemia is reversible if intensive treatment is instituted early," Drs. Byron E. Hall, Frank H. Krusen, and Henry W. Woltman write in the September 24 *J.A.M.A.*

"Early diagnosis, therefore, is essential," they add. "Treatment consists of administration of vitamin B_{12} and daily use of coordination exercises.

"The simple arrest or reversal of the degenerative changes by the administrat vitamin B_{12} without the use of a well-directe cise program will not accomplish return normal coordination and function of the extr as rapidly as when the exercises are added. start with the patient in the recumbent p become gradually more complex, and prog exercises given in the sitting and finally in th position."

The doctors base their conclusion on resul tained in treating 12 patients for degenerat the spinal cord associated with pernicious ane

MEDICAL NEWS

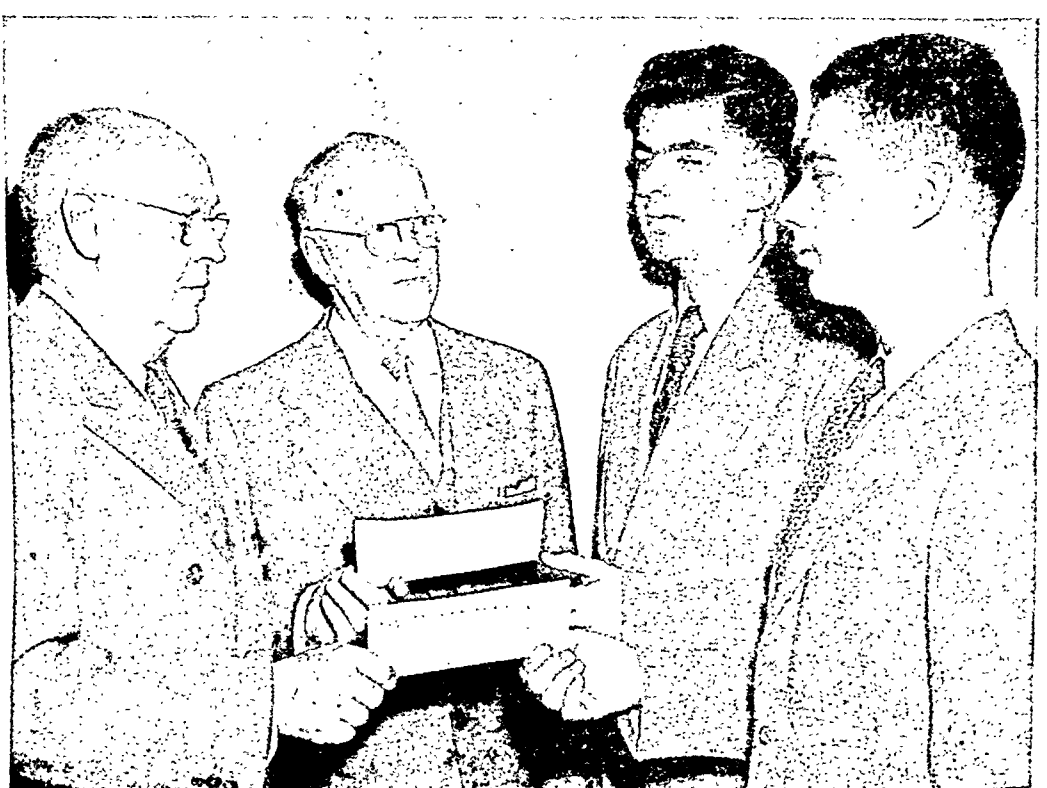
First War Memorial Scholarships Awarded

AS A tribute to 34 members who lost their lives while serving as medical officers in World War II, the Medical Society of the State of New York has announced through its War Memorial Committee the award of the first of a series of scholarships to provide for the education of their surviving children.

Ten young men and women, most of them now enrolled in schools and colleges, were the first to benefit under the provisions of a War Memorial Fund, created by the State Society by a $12 special assessment on each of its 23,000 members. There are 65 children of deceased medical officers from New York State eligible to benefit under the Fund. More than 5,100 members of the State Society were in service during the last war.

Dr. James F. Rooney, of Albany, chairman of the War Memorial Committee, estimated that the Fund will continue in operation until 1972, and will entail a total expenditure up to $328,000. He said scholarships will be awarded annually to each eligible survivor upon completion of his or her high-school education, if he or she pursues a collegiate or postgraduate professional course, up to the age of twenty-five.

Recipients of the first awards in the form of checks issued by Dr. James R. Reuling, of Bayside, treasurer of the State Society, were:



John R. Benfield, eighteen, a student at Columbia College. His father, Captain Richard Benfield, died in Calcutta, India, on October 8, 1945. His home is at 103 West 86th Street, New York City.

Mary Jean Buckmaster, twenty-two, who graduated this year from the University of Michigan. Her father, Major De Forest Buckmaster, died at Walter Reed Hospital, Washington, on February 3, 1945. Her home is at 609 Spring Street, Jamestown.

Franklin Brown, fourteen, a student at St. George's School, Middletown, Rhode Island. His father, Commander Clyde H. Brown, lost his life on April 12, 1945, at Okinawa. His mother is Mrs. Clyde H. Brown, of 33 Cranston Avenue, Newport, Rhode Island.

Lillian M. Haran, nineteen, a student at the University of Miami, at Miami, Florida. Her father, Captain Patrick S. Haran, died at Fort Jay Hospital on December 15, 1944. Her home is at 846 Prospect Place, Brooklyn.

Arthur E. Lyons, eighteen, a student at Columbia

Two future doctors receive War Memorial Scholarship awards. Left to right: Dr. James R. Reuling, State Society treasurer; Dr. John J. Masterson, State Society president; John R. Benfield, New York City, and Arthur E. Lyons, Flushing, both students at Columbia College.

York State. The Committee plans to extend the value of this book by inserting a considerable amount of material of interest to physicians, which will make them refer to the book more often and so increase its value to advertisers. That matter is still under discussion.

We hope that the next *Directory* will appear in December, 1950, and will be known as the 1951 edition.

Public Health and Education.—Dr. Curphey, chairman, sent a report stating he had attended meetings of subcommittees and arranged for post-graduate instruction and teaching days for several counties.

In connection with the activities of the Subcommittee on *Cerebral Palsy*, it was recommended that Dr. George W. Kosmak be included as a member.

It was voted that the recommendation be approved.

Public Relations.—Dr. Winslow, chairman, reported that during the past month the Public Relations Bureau took steps to reactivate the full-scale field program that had been halted temporarily during the summer. Mr. Leech, Mr. Tracey, and Mr. Weinrich returned to their stations and resumed activities. Coordination of the field program was placed in charge of Mr. Miebach, while Mr. Walsh was assigned to the speakers bureau and the Woman's Auxiliary.

He also reported on the various activities that took place during the month, such as releases on district branch meetings, publicizing an article in *Look* magazine, and Dr. Louis H. Bauer's speech to the National Association of Retail Druggists.

Veterans Administration, Liaison with.—Dr. Anderton reported that the contract between Veterans Medical Care Plan of New York, Inc., and the U. S. Veterans Administration had been extended for a year and that the salaries of the Coordinators had been reduced one quarter.

Woman's Auxiliary.—Dr. Beekman, chairman, reported as follows: As the National Education Campaign gains momentum, the value of the part our woman's auxiliaries, both State and county, are playing in relaying the medical profession's message to the American public becomes more evident.

Therefore, it is recommended that the Council authorize the Secretary to prepare a letter to the presidents of the county medical societies. This letter should contain the suggestion that, wherever practical, the chairman of each county and the State public relations committees extend an invitation to the chairman of the respective woman's auxiliaries' public relations committees to attend the meetings of his committee.

Approval was voted.

Workmen's Compensation.—Dr. Kenney, chairman, reported on the activities of the Committee.

New Business

Appointment of Committee on History of the Medical Society of the State of New York.—Dr. Anderton reported as follows: A Special Committee on the History of the Medical Society of the State of New York has been previously recommended and has been considered in conference by several members. Dr. Redway has written to the President suggesting that such committee consist of Dr. Fenwick Beekman, chairman, Dr. Nathan B. Van Etten, Dr. W. P. Anderton, Dr. Laurance D. Redway, and Dr. James F. Rooney, with Miss Dougherty as recorder.

It was voted that the Council request the President to appoint this committee.

The President so appointed.

Judge Proctor's Charge to the Jury in A.M.A. Case.—Judge Proctor states in simple and plain language what a membership society can and cannot do.

It was voted to send a letter from President Masterson to the president and secretary of each county society with a copy of Judge Proctor's charge to the jury in the suit of the Department of Justice against the Washington, D.C., Medical Society and the A.M.A. some years ago.

Political.—As the result of a memorandum read by Dr. Anderton,

It was voted to adhere to the policy that the Medical Society of the State of New York does not take active part as an organization in any political campaign.

VITAMIN B_{12}, EXERCISES AID VICTIMS OF PERNICIOUS ANEMIA

Spinal cord degeneration, which is one of the most sinister complications of pernicious anemia, can be reversed if treatment with vitamin B_{12} and exercises is begun early enough, say three doctors from the Mayo Clinic, Rochester, Minnesota.

"Our study indicates that degeneration of the spinal cord associated with pernicious anemia is reversible if intensive treatment is instituted early," Drs. Byron E. Hall, Frank H. Krusen, and Henry W. Woltman write in the September 24 *J.A.M.A.*

"Early diagnosis, therefore, is essential," they add. "Treatment consists of administration of vitamin B_{12} and daily use of coordination exercises.

"The simple arrest or reversal of the neurodegenerative changes by the administration of vitamin B_{12} without the use of a well-directed exercise program will not accomplish return toward normal coordination and function of the extremities as rapidly as when the exercises are added. They start with the patient in the recumbent position, become gradually more complex, and progress to exercises given in the sitting and finally in the erect position."

The doctors base their conclusion on results obtained in treating 12 patients for degeneration of the spinal cord associated with pernicious anemia.

College. His father, Lt. Commander Alfred L. Lyons, lost his life on April 28, 1945, on a hospital ship off Okinawa. His home is at 164-03 Crocheron Avenue, Flushing.

Robert J. Milne, nineteen, attending Hobart and William Smith Colleges, Geneva. His father, Major E. A. Milne, died at Strong Memorial Hospital, Rochester, on May 4, 1948. His home is at 23 Wolcott Street, Le Roy.

Lawrence G. Sachs, twenty-five, who finished third year law school at Harvard University in May. His father, Captain Harold M. Sachs, died at home on October 7, 1943. His home is at 1648 Madison Street, Brooklyn.

Clifford A. Schmiesing, eighteen, a student at Loyola University, Los Angeles, California. His father, Major Clifford A. Schmiesing, died on January 21, 1944, in Algeria. His home is at 1117 South Wilton Place, Los Angeles.

Fay M. Stevens, eighteen, a student at Elmira College, Elmira, and Charles L. Stevens, twenty, enrolled at Pennsylvania Military College, Chester, Pennsylvania. Their father, Lt. Commander Charles L. Stevens, died at Pensacola Naval Hospital on November 19, 1943. Their home is at 636 West Gray Street, Elmira.

Some of the students received retroactive awards, due to the fact that they became eligible under the provisions of the War Memorial Fund last year.

Members of the War Memorial Committee, of which Dr. Rooney is chairman, are Drs. Edward R. Cunniffe, of the Bronx; Maurice J. Dattelbaum, of Brooklyn, and Fenwick Beekman, of New York City.

MEDICALLY SPEAKING—

Electrical Transcriptions—The Bureau of Health Education of the American Medical Association has provided an excellent series of electrical transcriptions for use by medical societies and other interested groups. These should be extremely valuable as dramatic presentations by radio professionals derived from authentic medical sources and including a large variety of subjects. For further information address the Bureau at 535 North Dearborn Street, Chicago 10, Illinois.

Mobile Chest X-ray Unit—The first mobile chest x-ray unit of the Bureau of Tuberculosis of the New York City Department of Health was put into operation at Borough Hall, Brooklyn, on October 24. The new $25,000 mobile x-ray unit, housed in a 27-foot specially designed bus with a six-foot trailer carrying the generator, will be used in all five boroughs.

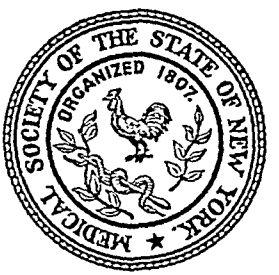
"The new unit will take the x-ray facilities of the Department of Health into even the remotest sections of the City," said Dr. Arthur B. Robins, director of the Department's tuberculosis bureau. "This new service is part of the continuous fight the Department of Health wages against tuberculosis," he explained. "The Bureau of Tuberculosis has steadily intensified its use of mass x-ray surveys to discover cases of tuberculosis in persons who do not realize they have the disease."

Elect District Branch Officers—Officers for the Second and Sixth District Branches of the Medical Society of the State of New York were elected at the annual meetings of the groups, held recently.

Meeting October 19 in Cortland, the Sixth District Branch elected the following officers, to serve for two years beginning at the adjournment of the 1950 House of Delegates: Dr. Norman C. Lyster, Norwich, president; Dr. Elton R. Dickson, Binghamton, first vice-preisdent; Dr. Gilbert M. Palen, Margaretville, second vice-president; Dr. James L. Palmer, Binghamton, secretary, and Dr. Robert H. Kerr, Cortland, treasurer.

At its meeting October 26 in Bronxville, the Second District Branch elected the following officers for the remainder of the current year and until the House of Delegates adjourns in 1951: Dr. Stephen R. Monteith, Nyack, first vice-president; Dr. Austin B. Johnson, Cedarhurst, second vice-president; Dr. John F. Rogers, Poughkeepsie, secretary, and Dr. Reid R. Heffner, New Rochelle, treasurer. Dr. Charles C. Murphy, Amityville, continues as president. Next year this branch will elect all their officers for the two ensuing years.

Postgraduate Instruction—On Monday, December 19, a program of postgraduate instruction will be given for the Geneva Academy of Medicine at the Bellhurst, Geneva, at 8:30 P.M. Dr. Foster Kennedy, professor of clinical medicine (neurology), Cornell University Medical College, will speak on "Psychiatric and Neurologic Problems in General Practice." The program has been arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York with the cooperation of the New York State Department of Health.



Course in Psychiatry—A course in "Psychiatry in General Medicine" will be given at the Mount Sinai Hospital, New York City, in affiliation with Columbia University, on Tuesday mornings, from 9 A.M. to 12 NOON, from January 3 to May 16, 1950, inclusive. The course is designed for the general practitioner with particular reference to the type of neuropsychiatric problems in general hospital and medical practice. Application may be made to the Registrar for Medical Instruction, Mount Sinai Hospital, Fifth Avenue and 100th Street, New York 29, New York.

To Give Lecture—The sixteenth Walter M. Brickner Lecture will be given at the Hospital for Joint Diseases, New York City, by Dr. Ephraim Shorr, associate professor of medicine, Cornell University Medical College, on Tuesday, December 27, at 8:30 P.M. The subject of the lecture will be, "Some Aspects of Skeletal Metabolism and Renal Calculus Formation."

Military Surgeons to Meet—A joint meeting of the Metropolitan New York Chapter, Association of Military Surgeons, and the New York Academy of Medicine will be held Friday night, January 6, 1950, at 8:30 P.M. at the New York Academy of Medicine, New York City. Chairman of the meeting will be Dr. Harold R. Merwarth, president of the Metropolitan Chapter. The program will include the following: "Civilian Health, a Joint Responsibility," Dr. Warren P. Dearing, deputy surgeon general, U. S. Public Health Service, and "Recent Advances in Electronic Microscopy, Dr. Ralph Wykoff, scientist director, National Institutes of Health, U.S. Public Health Service, Bethesda, Maryland.

Subject and Departmental Index

Articles

Abortion, catheter found in peritoneal cavity following, 2847
Acute Hemolytic Crisis Complicating Eclampsia (Langsam and Carpenter), 2442
Acute Laryngeal Edema in Nephritis (Bernstein), 2188
Acute Myocardial Infarction in a Sixteen-Year-Old Boy (Douglas and Marienberg), 2845
Adenoma of Bartholin's Gland (Lazarus and Lazarus), 1577
Adenomas, papillary, of the rectum, 1791
Administration of Curare by Electrophoresis (Neuwirth), 1569
Alcoholic patients, needle biopsy of the liver in, 2677
Allergic disorders of infants and children, antihistaminic therapy of, 2313
Amebic dysentery, relation of, to chronic ulcerative colitis, 1795
Amputee, arm, rehabilitation of the, 1921
Amyotrophic lateral sclerosis, rectal administration of tolserol in, 2190
Analgesia and anesthesia for obstetrics, spinal, critical appraisal of [Panel Discussion: Obstetric Anesthesia], 1527
Anastomosis, ureterosigmoid, by direct elliptic connection, 2933
Anemia: *see* Pernicious Anemia
Anesthesia: *see* Panel Discussion: Obstetric Anesthesia
Aneurysm, dissecting, with rupture into the pericardial sac, 2566
Angiocardiography, cardiac catheterization and, in diagnosis of congenital cardiac lesions, 1713
Anorectogenital Lymphogranuloma Venereum and Granuloma Inguinale Treated with Aureomycin (Prigot, Wright, Logan, and deLuca), 1911
Anthracosilicosis, unusual case of, 2667
Antibiotic Therapy
  recent advances, 1797
  see also: Penicillin
Anticoagulant therapy, 1687
Antihistaminic drugs, failure of, to inhibit Diodrast reactions, 2556
Antihistaminic Therapy of Allergic Disorders in Infants and Children (Kugelmass), 2313
Aorta, mediastinal cystic necrosis of, 2566
Apoplexy, cerebral, mechanism and differential diagnosis, 2153
Appendices epiploicae, torsion of, 2168
Application of Sponge Biopsy for Cancer Diagnosis in Office Practice (Gladstone), 2687
Arrhythmias, use of intravenous quinidine during clinical anesthesia for treatment of, 1554
Arteries, major, injuries to, and their treatment, 2039
Arteriosclerotic heart and peripheral vascular disease, vitamin E in, 2422
Arthritis, rheumatoid, subcutaneous cysts of, 1566
Asthma, bronchial, death in a case of, treated successively with intravenous procaine and sodium amytal, 2841
Atresia of the small intestine, congenital, 2439
Aureomycin, anorectogenital lymphogranuloma venereum and granuloma inguinale treated with, 1911
Aureomycin in the Treatment of Virus Pneumonia (Cuthbert) 2701

BAL toxicity during treatment of gold glossitis, 1965
Barton forceps, experience with, 1825
Basis of Treatment in the Postphlebitic Syndrome (Glasser), 1923
Blind, Commission for the, of the State Department of Health, function of, 2389
Biopsy of the liver, needle, in alcoholic patients, 2677
Biopsy, sponge, for cancer diagnosis in office practice, 2687
Brenner Tumor (Kushner), 1573
Brucellosis, chronic, complicated by severe pancytopenia, 2181

Cancer and Cardiovascular Diseases (Foldes), 2563
Cancer
  diagnosis in office practice, sponge biopsy for, 2687
  metastatic, localization of, by trauma, 1839

prevention and detection centers, 1944
see also: Carcinoma
Capillary fragility, hesperidin-C and, 1823
Carcinoma
of the esophagus, esophagogastrostomy for, 2559
of the lower portion of the colon and rectum, selection of operation for, 2919
of the skin and lips [Symposium: Precancerous and Cancerous Dermatoses of the Skin], 1659
Cardiovascular diseases, cancer and, 2563
Case of Acute BAL Toxicity During Treatment of Gold Glossitis (Zarowitz and Nelson), 1965
Catheterization, cardiac, and angiocardiography in diagnosis of congenital cardiac lesions [Symposium: Surgical Treatment of Heart Disease], 1713
Catheter Found in Peritoneal Cavity Following Abortion (Ficarra), 2847
Caudal anesthesia, continuous, in obstetrics [Panel Discussion: Obstetric Anesthesia], 1531
Cecostomy in Large Bowel Obstruction Associated with Megacecum (Ficarra), 2191
Central Placenta Previa with Missed Labor (Bird and Nemser), 1835
Cerebral Apoplexy: Mechanism and Differential Diagnosis (Zimmerman), 2153
Cerebral Edema Complicating Active Rheumatic Heart Disease in a Child (Kowaloff), 2183
Cerebral Palsies: Their Diagnosis, Classification, and Treatment (Dugan), 2535
Cerebral palsy, problem of, 2793
Cerebrospinal Fluid Examination in Diagonisis of Multiple Sclerosis (von Storch, Harris, and Layer), 2145
Cesarean section, extraperitoneal, 2295
Chest x-ray survey [Symposium: Methods of Tuberculosis Case-Finding in the Community], 2775
Chest x-ray survey, Niagara Falls [Symposium: Methods of Tuberculosis Case-Finding in the Community], 2779, 2783
Children, management of ear problems in, 2825
Chronic Thyrotoxic Myopathy (Rinzler and Marder), 2573
Chronic Brucellosis Complicated by Severe Pancytopenia (Mishkin), 2181
Clinical Aspects of Congenital Cardiac Lesions Amenable to Surgical Therapy [Symposium: Surgical Treatment of Heart Disease] (Baldwin), 1707
Clinical Evaluation of Ethinyl Estradiol in the Menopause (Dubrow, Poole, and Walter), 1828
Clinicopathologic Conferences, 2566
Colitis
segmental, associated with rheumatic fever, 1702
ulcerative, 1782
see also: Ulcerative Colitis
Colles' fracture, comminuted, treatment by ulnar styloid resection, 2540
Colon and rectum, lower portion of, selection of operation for carcinoma of, 2919
Colonic Dysfunction (Jordan), 1802
Colon, review of, for years 1947–1948 at Binghamton City Hospital, 1821
Comminuted Colles' fracture, treatment by ulnar styloid resection, 2540
Commission for the Blind of the State Department of Social Welfare, functions of, 2389
Comparison Between Various Forms of Psychosurgery [Symposium: Psychosurgery] (Mettler), 2283
Complete Versus Supravaginal Hysterectomy (Irons), 1951
Congenital Atresia of the Small Intestine (Cantor), 2439
Congenital cardiac lesions amenable to surgical therapy [Symposium: Surgical Treatment of Heart Disease], 1707
Continuous Caudal Anesthesia in Obstetrics [Panel Discussion: Obstetric Anesthesia] (Herzlich), 1531
Convulsive Reaction Pattern (Simons), 2074
Coronary artery disease, Master "2-step" exercise test in the differential diagnosis of, 2843
Correction of Deformities of the Nose Associated with Nasal Obstruction (Whitham), 2413
Counterimmunization, Rh, 2299
County society members, role of, in medical legislation, 2704
Coxitis due to Escherichia Coli (Petersen), 2835
Critical Appraisal of Spinal Analgesia and Anesthesia for Obstetrics [Panel Discussion: Obstetric Anesthesia] (Greene), 1527
Curettage, unusual sequel to, in the puerperal uterus, 2441
Cutaneous Leishmaniasis—Report of a Case and Summary of the Newer Concepts (Winer), 1671

Deafness as It Occurs in Various Age Groups (Nash), 2409
Death in a Case of Bronchial Asthma Treated Successively with Intravenous Procaine and Sodium Amytal (Gelfand, Mufson, and Richman), 2841
Death, relative importance of leading causes of, in New York City, 2956
Defects in the Visual Fields Resulting from Increased Intracranial Pressure (Rucker), 2417
Deformities of the nose associated with nasal obstruction, correction of, 2413
Diabetes Control in the Public Health Program (Wilkerson), 2945
Diabetes mellitus, vascular degeneration in, 2055
Diabetic crisis, pregnancy complicated by, 2699
Diagnosis of malignant cells in serous fluids, sputa, and bronchial secretions, review of, 2673
Diaphragmatic Hernia Through the Foramen of Morgagni (Johnson), 1842
Diarrhea of the Newborn (Trussell), 2789
Dicumarol, use of, in acute myocardial infarction, 2694
Diodrast reactions, failure of antihistaminic drugs to inhibit, 2556
Diphtheria Immunity in High School Seniors (Lane and Holla), 2548
Discussion of Cancer Prevention and Detection Centers (Goldman), 1944
Discussion of the Various Surgical Procedures Employed in the Management of Portal Hypertension (Lord), 2064
Dissecting (Intramural) Diverticulitis (Cohen), 2661
Diuretics, mercurial, untoward effects of, 2429
Diuretics, organic mercurial, toxic nephrosis from, 2319
Diverticulitis, dissecting (intramural), 2661
Diverticulum, Meckel's, 2309

Early Recognition of Possibly Dangerous Nevi (Moles) and the Best Procedure to Avoid Development of Malignant Melanomas (Nevocarcinoma) [Symposium: Precancerous and Cancerous Dermatoses of the Skin] (Traub), 1661
Ear problems, management of, in children, 2825
Eclampsia, acute hemolytic crisis complicating, 2442
Ectopic Pregnancy with a Study of an Associated Clinical Syndrome (Ingraham, Gardner, and Witkin), 1562
Electrocardiographic Changes in Malaria (Greenfield), 2839
Electrophoresis, administration of curare by, 1569
Electrosurgical snare, sigmoidorectal, 2311
Erythroblastosis Fetalis due to Blood Group A-B-O Incompatibility (Tisdall and Hartnett), 1699
Erythrocyte regeneration in pernicious anemia, 2158
Encephalitis in Children with Electroencephalographic Changes (Shinners, Krauss, and Rochester), 2140
Endocarditis, bacterial, penicillin prophylaxis of, 1693
Endometriosis of the Sigmoid (Berlin and Finestone), 2081
Escherichia coli, coxitis due to, 2835
Esophagus, carcinoma of the, esophagogastrostomy, 2559
Esophagogastrostomy, high cervical, for carcinoma of the cervical esophagus, 2559
Ethinyl estradiol in the menopause, 1828
Etiology and Treatment of Pancreatitis (Doubilet and Mulholland), 2038
Etiology of Poliomyelitis (Dalldorf), 2053
Exercise test, Master "2-step", in the differential diagnosis of coronary artery disease, 2843
Experiences with Anticoagulant Therapy (Boller, Quigley, Tarpey, and Harris), 1687
Experience with the Barton Forceps in a Small Urban Hospital (Barton), 1825
Extraperitoneal Cesarean Section: Is There Still a Need for It? (Nelms), 2295
Extrinsic disease, genitourinary symptoms due to, 2953

Failure of Antihistaminic Drugs to Inhibit Diodrast Reactions (Crepea, Allanson, and DeLambre), 2556
Failures in Retinal Detachment Surgery (Koenig), 2405
Femoral neck fracture, ununited, method of fixation for, 1963
Femur, fractures of, in children, 2541
Fetal risk, trend toward reduction of, in obstetrics, 2070
Five-Day Ambulatory Penicillin Therapy of Early Syphilis (Rausch), 1668
Fixation of ununited femoral neck fracture, 1963
Foreign Body (Needle) in Heart (Friedlander, Brodman, and Smith), 1837
Fractures of the Femur in Children (Potts and Dunham), 2541
Frontal lobotomy, successes and failures following [Symposium: Psychosurgery], 2263
Fulminating Meningococcemia (Waterhouse-Friderichsen Syndrome) with Recovery (Brand), 2837
Functions of the Commission for the Blind of the State Department of Social Welfare (Gillette), 2389
Fungous Infections of the Skin and Scalp: A New Approach to Their Treatment (Reiss and Dougherty), 1939
Furacin, sensitivity to, 2325

Gangrene of Entire Large Bowel to Distal Sigmoid Following Volvulus of Hepatic Flexure (Avitabile and Fiorentino), 2321
Gastrectomy, pernicious anemia following, 2437
Gastric Malignancy (Morton), 2915
Gastric Resection for Peptic Ulcer in Poor-risk Patients (Stewart, Hale, and Hix), 2911
Gastroenteritis in Man due to a Filtrable Agent (Gordon, Ingraham, Korns, and Trussell), 1918
Genitourinary Symptoms due to Extrinsic Disease (Kennedy), 2953
Glossitis, gold, acute BAL toxicity during treatment of, 1965
Granuloma inguinale treated with aureomycin, 1911
Granulosa cell tumors of the ovary, spontaneous rupture of, 2305

Hay Fever as a Public Health Problem (Lazarowitz), 1960
Hemolytic crisis, eclampsia complicating, 2442
Hemopneumothorax, spontaneous, 2185
Hemorrhage: *see* Postpartum Hemorrhage
Hemorrhoidectomy, spontaneous rupture of a varix of the internal jugular vein following, 2435
Hematologic Disorders (Allen), 1956
Hematoma of the Umbilical Cord (Schwartz), 1575
Hernia, diaphragmatic, through foramen of morgagni, 1842
Hesperidin-C and Capillary Fragility (Loughlin), 1823
High Cervical Esophagogastrostomy for Carcinoma of the Cervical Esophagus Extending into the Superior Mediastinum: Value of a Right-sided Thoracoabdominal Approach (Lord and Localio), 2559
House of Delegates (Andresen), 1968
Hydronephrosis Revealed by Trauma (Baretz), 2445
Hypertension, portal, surgical procedures employed in the management of, 2064
Hysterectomy
  complete versus supravaginal, 1951
  postpartum hemorrhage necessitating, 2323

Ileitis: *see* Regional Ileitis
Ileojejunitis (Crohn), 1808
Immunity, diphtheria, in high school seniors, 2548
Incidence of Valvular Heart Disease in People over Fifty and Penicillin Prophylaxis of Bacterial Endocarditis (Lichtman and Master), 1693
Indications for Operation in Patent Ductus Arteriosus (With Special Reference to Adults) [Symposium: Surgical Treatment of Heart Disease] (Touroff), 1722
Inhalation Anesthesia in Obstetrics [Panel Discussion: Obstetric Anesthesia] (Jahraus), 1535
Injuries to Major Arteries and Their Treatment (Linton), 2039
Intern and residency training, suggestions to improve, and to facilitate intern placement by rearrangement of schedule, 2960
Intestinal obstruction in infancy, 1691
Intracranial pressure, increased, defects in the visual fields resulting from, 2417

Laryngeal edema, acute, in nephritis, 2188
Lateral sclerosis, amyotrophic, rectal administration of tolserol in, 2190
Legislation, medical, role of county society members in, 2704
Leishmaniasis, cutaneous, 1671
Lipomatosis, renal, 2924
Liver, needle biopsy of, in alcoholic patients, 2677
Lobotomy, frontal, successes and failures following [Symposium: Psychosurgery], 2263
Localization of Metastatic Cancer by Trauma (Pack and Booher), 1839
Lymphogranuloma venereum, anorectogenital, treated with aureomycin, 1911

Malaria, electrocardiographic changes in, 2839
Malignancy, gastric, 2915
Malignant cells, diagnosis of, in serous fluids, sputa, and bronchial secretions, 2673
Management of Ear Problems in Children (Jones), 2825
Management of the Symptom Complex in Acute Poliomyelitis (Smith, Graubard, and Rosenblatt), 2655
Mass Chest X-ray Survey [Symposium: Methods of Tuberculosis Case-Finding in the Community] (Schuck and Ames), 2775
Massive Intestinal Resection for Regional Ileitis (Weinstein and Roberts), 2577
Master "2-Step" Exercise Test in the Differential Diagnosis of Coronary Artery Disease (Storch, Pordy, and Kolker), 2843
Maternal deaths in New York City in 1947, study of, 1676
Meckel's *Diverticulum* (Hyman and Gumport), 2309
Mediastinal Cystic Necrosis of the Aorta and Dissecting Aneurysm with Rupture into Pericardial Sac (Bellevue), 2566
Megacecum, large bowel obstruction associated with, 2191
Melanomas, malignant, best procedure to avoid development of [Symposium: Precancerous and Cancerous Dermatoses of the Skin], 1661
Meningococcemia, fulminating, with recovery, 2837
Menopausal Syndrome (Hock), 2078
Menopause, ethinyl estradiol in, 1828
Mesencephalothalamotomy, thalamotomy and [Symposium: Psychosurgery], 2275
Metabolic Aspects of Vascular Degeneration in Diabetes Mellitus (Anderson), 2055
Methemoglobinemia, well water, 2576
Method of Fixation for Ununited Femoral Neck Fracture (Lusskin and Freund), 1963
Methylguanidine, blood, in poliomyelitis, 1685
Migraine Headache Treated Successfully by Head-Traction Manipulation and Thiamin Chloride (Braaf), 1812
Migraine Problem (Friedman), 1831
Mortality, neonatal, pediatric suggestions to reduce, 2829
Multiple Sclerosis
  cerebrospinal fluid examination in, 2145
  diagnosis of, 2425
Myocardial Infarction
  in a sixteen-year-old boy, 2845
  use of Dicumarol in, 2694
Myopathy, chronic thyrotoxic, 2573

Nasal obstruction, correction of deformities of the nose associated with, 2413
National Hospital for Speech Disorders, Postlaryngectomy Clinic of, 2398
Necrosis of the aorta, mediastinal cystic, and dissecting aneurysm with rupture into the pericardial sac, 2566
Needle Biopsy of the Liver in Alcoholic Patients (Sanes, Bahn, Chapple, and Chassin), 2677
Neonatal mortality, pediatric suggestions to reduce, 2829
Nephritis, acute laryngeal edema in, 2188
Nephrosis, toxic, from organic mercurial diuretics, 2319
Neuritis and Neuronapathy in Industrial Medicine (Perkins), 2149
Neuronapathy, neuritis and, in industrial medicine, 2149
Neuropsychiatric Diagnosis (Bigelow), 2172
Nevi, early recognition of possibly dangerous [Symposium: Precancerous and Cancerous Dermatoses of the Skin], 1661
Newborn, diarrhea of the, 2789
Niagara Falls Mass Chest X-ray Survey—Community Organization [Symposium: Methods of Tuberculosis Case-Finding in the Community] (Campbell, Siegal, and Wirth), 2779
Niagara Falls Mass Chest X-ray Survey—Procedures and Results [Symposium: Methods of Tuberculosis Case-Finding in the Community] (Siegal, Wirth, and Campbell), 2783

Obstetrician's View of Modern Anesthesia [Panel Discussion: Obstetric Anesthesia] (Siegler), 1538
Obstetrics: *see* Panel Discussion: Obstetric Anesthesia
Obstruction, intestinal, in infancy, 1691
Old Age (Klumpp), 1929
Omentum, torsion of, 1571
On the Diagnosis of Multiple Sclerosis (Kennedy), 2425

WE ARE MANAGEMENT MEN, NOT MEDICINE MEN

. . . but we do cure headaches . . . prevent worries resulting from inefficient property management.

The cost is nominal, far less than you would expect to pay for a *reliable* specialist.

Freedom from worry . . . profitable returns on your real estate investment are the results.

Consult us without obligation—today!
